ABSTRACT

The 7th annual E-Learn world conference on e-learning in corporate, government, healthcare, and higher education organized by the Association for the Advancement of Computing in Education (AACE) includes more than 600 papers. Papers from this proceedings come from contributors representing more than 50 countries, sharing their perspectives and experiences with electronic learning in elementary, secondary, and postsecondary education. Topics include: military training; course Web site creation; instructional design; new trends in health care and medicine; information and knowledge dissemination; knowledge management; learning repositories; instructional innovation and activities design; cognitive style; virtual communities; issues in e-government; success in distance education; computer system design; the Internet-connected classroom; teachers' and facilitators' roles; computer software development; professional development; distance education quality; usability tests and use studies; ethical issues; standards; student evaluation; collaboration; evaluation frameworks; theory and practice; instructional strategies; teleconferencing; search strategies; virtual reality; instructional effectiveness; instructional material design; computer simulation; gender equity; digital libraries; instruction for individuals with disabilities; technology integration; multimedia materials; and information skills development. INVITATION

E-Learn 2003 — World Conference on E-Learning in Corporate, Healthcare, Government, and Higher Education is an international conference organized by the Association for the Advancement of Computing in Education (AACE). This annual conference series serves as a multidisciplinary forum for the exchange of information on the research, development, and applications on all topics related to E-Learning.

Information for Presenters

Details of presentation formats are given on the following pages. The general principles applying to all are:

- All communication will be with the principal presenter who is responsible for communicating with co-presenters of that session.
- The conference will attempt to secure all equipment for presenters, with the exception of poster/demonstration presenters. However, where special equipment is needed, presenters may need to bring or rent equipment. The name of a rental firm can be provided.
- All presenters must register and pay the registration fee. Early registration fee will be approximately $395 (US) with a discount for AACE members.

Proceedings

Accepted papers will be published in the Proceedings (book and CD-ROM formats) as well as in the AACE Digital Library. These proceedings serve as major sources of information and reflect the current state of the art for the E-Learning community. In addition, selected papers may be invited for publication in AACE's respected journals especially in the *International Journal on E-Learning*. See: www.aace.org/pubs

Paper Awards

All presented papers will be considered by the Program Committee for Outstanding Paper Awards. There will also be an award for Outstanding Student Paper (therefore, please indicate if primary author is a full-time student).

Hotel & Travel Arrangements

Special hotel room rates will be available to conference attendees. Discount airfares will be available from a designated airline carrier.

Background

The E-Learn Conference series originated as the WebNet World Conference on the WWW and Internet which was held as a major international conference in San Francisco, CA (1996); Toronto, Canada (1997); Orlando, Florida (1998); Honolulu, HI (1999); San Antonio, TX (2000); Orlando, FL (2001); and Montréal, Canada (2002). E-Learn 2003 is the eighth in this series of internationally respected events.

Corporate Participation

A variety of opportunities are available to present research-oriented papers or to showcase and market your products and services.

E-Learn is Unique

The E-Learn Conference series is an international forum designed to facilitate the exchange of information and ideas on the research, issues, developments, and ap[illegible] of a broad range of E-Learning topics.

E-Learn is a[illegible] collaboration between E-Learning researchers and practitioners fr[illegible]porate, government, healthcare, and higher education sectors. All p[illegible]proposals are reviewed and selected by a respected international Pro[illegible]mmittee, based on merit and the perceived value for attendees.

Broad Range of Important Topics: Coverage of a wide range of interrelated topics is just one of the features that distinguishes the E-Learn conference series. Attendees are able to mix and match sessions to focus on the combination of topics that are of the most interest, concern and benefit to them.

Participatory Event: While there are Keynote and Invited talks delivered by internationally recognized technology experts, E-Learn is more of a participatory event. This means that all attendees play an important, interactive role, offering valuable feedback and insight gained from their own experiences. The atmosphere at E-Learn is exciting and energizing. A wealth of knowledge is gathered and exchanged, as professionals from disparate but related fields come from all over the world to meet one-on-one or in small groups and learn about new developments that impact their respective activities.

Not a Trade Show: While E-Learn does encourage commercial participation, it is not a trade show, and there is not an exhibition. Instead, the conference uniquely relates and displays commercial activities throughout the E-Learn program in the form of Corporate Showcases and Demonstrations and other presentations by companies.

900+ Participants
from 50 Countries

TOPICS

The scope of the conference includes, but is not limited to, the following topics as they relate to E-Learning in Corporate, Government, Healthcare, and Higher Education.

Application Domains

- General & Cross-Domain
- Corporate
- Government
- Health Care
- Higher Education
- Informal Learning (Museums, Communities, Homes)
- K-12
- Military Training
- Professional Associations & Non-Profits

Major Topics relating to or technologically supporting E-Learning

- Content Development
- Evaluation
- Implementation Examples and Issues
- Instructional Design
- Policy Issues
- Research
- Social and Cultural Issues
- Standards and Interoperability
- Tools and Systems
- Other

BEST COPY AVAILABLE

SUBMISSION INFORMATION

FULL PAPERS

Presentation time: 25 minutes
Submission length: 4-6 pages (2,500-3,750 words)
Proceedings length: 6 pages maximum
AV equipment provided: PC, Projector, Internet, VCR

Papers present reports of significant work or integrative reviews in research, development, applications, and societal issues related to all aspects of the conference topics.

Systems & Resources

Papers related to projects, technical developments, systems, and resources.

The paper should include:

- Whether this work is just beginning, on-going, or completed;
- The partners involved;
- The major goals and the basic approach - this includes the educational problem addressed or the new educational opportunity created;
- A brief review of previous work as a background;
- A clear description of what has been developed, including schematic overviews and screen dumps (if applicable);
- Any validation (usability testing, pilot testing, expert evaluation, etc.) that has taken place; and
- Future work and implications for others.

The reference list for this kind of paper should include URLs for the work, and at least a few literature references.

Conceptual & Empirical Studies

Reviews, conceptual overviews, evaluations, and empirical studies.

The paper should include:

- The topic;
- The motivation for the work;
- The major questions addressed;
- The general process and conceptual framework, with references to literature;
- The concrete method, with sufficient detail on instruments and procedures;
- Major points or results; and
- Implications.

This paper category requires a strong and up-to-date well synthesized literature review, with work from a variety of sources (not just the research team of the author), and also an appropriate writing and presentation style for a scholarly review or overview.

Case Studies

Papers related to local experiences (e.g., a course or a prototype tested in a local situation).

The paper should include:

- The most important features of the context;
- A description of the problem in both local and conceptual terms;
- A description of who, what, why, and how, including screen dumps if relevant;
- Implications for the local setting or the local prototype; and
- Implications for others outside the local setting.

This paper category should include a reference list with relevant URLs, and a few citations to papers related to the local problem, but from outside the local setting. The latter is to indicate that the author can see the local situation in a broader and more general context.

Other

For authors who do not feel they fit in any of the above. The Program Committee may request that the author revise the paper to relate to one of the above categories, or may accept it as submitted.

BRIEF PAPERS

Presentation time: 15 minutes
Submission length: 2-3 pages, 1,250-1,875 words
Proceedings length: 2 pages maximum
AV equipment provided: PC, Projector, Internet, VCR

These papers are brief, more condensed presentations or work-in-progress projects.

New Developments

Descriptions of new extensions to existing projects or newly initiated projects.

Project Opportunities

Descriptions of projects underway that include opportunities for additional project partners.

Demonstrations

Other

For authors who do not feel they fit in any of the above. The Program Committee may request that the author revise the paper to relate to one of the above categories, or may accept it as submitted.

The submission should include:

- What is going to be shown or demonstrated or offered;
- The major aspects;
- The context or motivation; and
- Relevant URLs or literature references.

PANELS

Presentation time: 1 hour
Submission length: 2-3 pages, 1,250-1,875 words
Proceedings length: 4 pages maximum
AV equipment provided: PC, Projector, Internet, VCR

A panel offers an opportunity for 3-5 people (including the chair) to present their views or results on a common theme, issue, or question and discuss them with the audience. Panels should cover timely topics related to the conference areas of interest. Panel selection will be based on the importance, originality, focus, and timeliness of the topic; expertise of proposed panelists; as well as the potential for informative (and even controversial) discussion.

Panels must allot at least 50% of the time for interaction and discussion with the audience.

The panel proposals should include:

- Description of the panel topic, including why this topic is important to Conference attendees; and
- Brief position statement and qualifications of each panelist.

ROUNDTABLES

Presentation time: 1 hour
Submission length: 2-3 pages, 1,250-1,875 words
Proceedings length: 150 words (to be published only in Abstract Book)
AV equipment provided: electricity

These sessions allow maximum interaction in informal, small-group discussions on a single topic. The format is appropriate for papers, projects, or works-in-progress that encourage discussion. Roundtables share a room with 2-3 other concurrently held Roundtables.

VIDEO FESTIVAL

Presentation time: 1 hour
Submission length: 2-3 pages, 1,250-1,875 words
Proceedings length: 2 pages
AV equipment provided: VCR, PC, Projector, Internet

The field has matured to the point that we have a growing number of video resources – cases, classroom/training video clips, and many other forms. Presenters should have a short handout on the video and use most of the time showing the video.

BEST COPY AVAILABLE

SUBMISSION INFORMATION

INTERACTIVE SESSIONS

Presentation time: 1 hour
Submission length: 2-3 pages, 1,250-1,875 words
Proceedings length: 3 pages
AV equipment provided: PC, Monitor, Internet

If you have mastered a new piece of software (or a new version) that others would be interested in learning about, submit a proposal for an Interactive Session. In this informal session, you will demonstrate the software, illustrate the process of using it, show participants some of the complexities and tricks about it, and give them an opportunity to try it themselves.

These sessions are also appropriate for instructional strategies, procedures, and evaluation procedures. The idea is not to give a definitive workshop on the topic, but to provide participants with enough information to help them decide whether their needs can be met with the program or procedure.

Include a description of the software to be used by participants, the objectives of the session, and the intended audience (experience level and prerequisites). These presentations share a room with 2-3 other concurrently held Interactive Sessions.

TUTORIALS / WORKSHOPS

Presentation time: 3.5 or 7 hours
Submission length: see information below
Proceedings length: no pages
AV equipment provided: PC, Projector, Internet (Tutorial);
PC, Projector, PC Lab, Internet (Workshop)

Tutorials and Workshops are intended to enhance the skills and broaden the perspective of their attendees. They should be designed to introduce a rigorous framework for learning a new area or to provide advanced technical training in an area. Submissions will be selected on the basis of the instructors' qualifications for teaching the proposed Tutorial or Workshop and their contribution to the overall conference program. Workshops differ from Tutorials by involving hands-on experience with hardware/software provided.

Note: Few Workshops are selected because a lab of equipment is required for each. If you submit a Workshop proposal, please indicate if your proposal is also appropriate for presentation as a non-hands on Tutorial.

Tutorial/Workshop proposals should include:

- Clear description of the objectives;
- Intended audience (experience level and prerequisites);
- Proposed length (3.5 hours or 7 hours);
- 200-word abstract;
- 1-page topical outline of the content; and
- Summary of the instructor's qualifications.

POSTER / DEMONSTRATIONS

Presentation time: 2 hours
Submission length: 2-3 pages, 1,250-1,875 words
Proceedings length: 2 pages
AV equipment provided: 4'x8' poster board, 6' table, 2 chairs, electricity, Internet if wireless card & PC brought

Poster/Demonstration sessions enable researchers and non-commercial developers to demonstrate and discuss their latest results and developments in progress in order to gain feedback and to establish contact with similar projects.

Poster/Demonstration proposals should include:

- Description of the planned Poster/Demonstration; should emphasize the problem, what was done, and why the work is important.

Poster/Demonstration presenters will be required to arrange for their own systems software and hardware.

CORPORATE DEMONSTRATIONS/ LITERATURE

Presentation time: 2 hours
Submission length: 1-2 paragraphs
Proceedings length: no pages
AV equipment provided: 4'x8' poster board, 6' table, 2 chairs, electricity, Internet if wireless card & PC brought

Demonstrate and discuss your company's products, services, developments, applications and research, inform the audience of your future directions, gain feedback, and establish contacts.

Scheduled with Poster/Demonstrations grouped together in open exhibition-style, usually all in one hall. This is an informal event with a circulating conference-wide audience. Sales are permitted. You may stock and sell your product at your table.

CORPORATE SHOWCASES

Presentation time: 30 minutes
Submission length: 1-2 paragraphs
Proceedings length: 150 words (to be published only in Abstract Book)
AV equipment provided: PC, Projector, Internet, VCR

Demonstrate and discuss your company's products, services, developments, applications and research, inform the audience of your future directions, gain feedback, and establish contacts.

Scheduled concurrently only with other Showcases. Presentation rooms generally accommodate 50-150 people, theatre-style. This is more of a formal presentation than the Corporate Demonstration.

SIG (SPECIAL INTEREST GROUP) DISCUSSIONS

Presentation time: 1 hour
Submission length: 1-3 pages (625-1,875 words)
Proceedings length: no pages
AV equipment provided: PC, Projector, Internet, VCR

To encourage informal interaction among individuals with common interests, SIG discussion groups will be formed based upon proposals accepted under the Call for Participation. Also, new SIG discussion groups may be formed either formally or on an impromptu basis when at the conference.

SIG Discussion proposals should include:

- Description of the discussion topic emphasizing the problem or issue and why the work is important; and
- Indication of whether you are willing to chair the discussion.

SUBMISSION REQUIREMENTS

Submit all proposals by completing the Web form at: http://www.aace.org/conf/elearn

All proposals must be submitted by uploading PDF, Word, RTF, or Postscript file using the Web form. No hard copy paper, faxed, or e-mail submissions will be accepted.

Please send your proposal only ONE time.

Questions? Contact AACE at:
Phone: 757-623-7588
Fax: 703-997-8760
E-mail: conf@aace.org
www.aace.org/conf/edmedia

Phoenix Arizona

Offering unique Southwest culture and a desirable climate, Phoenix is located along the banks of the Salt River, where early Hohokam Indians first settled. Phoenix, the state's capital, is saddled between dramatic mountain ranges.

Year-round sunshine and mild autumn temperatures make Phoenix an ideal location for E-Learn 2003. This premier desert city is located 1,117 feet above sea level and the weather is warm, sunny and usually dry.

ATTRACTIONS/NIGHTLIFE/PERFORMING ARTS: A variety of museums offer indigenous history and art, as well as imported works. The Heard Museum in downtown Phoenix is well known for its Native American art exhibits. The Phoenix Art Museum, host of the Cowboy Artists Show, has a permanent collection of 16,000 paintings, sculptures, costumes and other works of art from the 15th through 20th centuries. Other interesting and informative museums are the Arizona Science Center, the Phoenix Museum of History, the Hall of Flame Fire Fighting Museum, Scottsdale Center for the Arts and the Champlin Fighter Aircraft Museum.

With 20 theater groups in the area, there is no shortage of entertainment. Phoenix offers everything from Broadway plays to lyric opera. The Herberger Theater Center plays host to many fine performances, including Ballet Arizona, the Arizona Opera Company and the Arizona Theatre Company.

The Phoenix Symphony Orchestra has been performing for more than 35 years with a season that runs from fall through spring. There are many opportunities to enjoy other music as well, including rock, jazz, country and more.

SIGHTSEEING: Arizona is known for its contrasts. Visitors will see everything from northern Arizona's tall, cool pines to the cactus-filled scenery of the Sonoran Desert. And if there's a "must-see," it's Arizona's majestic Grand Canyon, one of the world's seven natural wonders. This breathtaking sight is open year-round and may be experienced through nature walks or mule rides into the Canyon, or by taking a leisurely drive along its outer edges. Before reaching the Grand Canyon, be sure to stop at Sedona, a cultural community providing a wide array of boutiques and art galleries selling everything from Native American and Southwestern arts and crafts to fine jewelry.

Arizona also is home to Lake Powell on the northern border. Lake Powell is 186 miles long and has more miles of shoreline than the entire Pacific coast of the United States. The lake, which extends into southern Utah. Located in eastern Arizona, the White Mountains stand at an elevation of some 9,000 feet. The White Mountains are rich in trout-stocked lakes. With temperatures about 30 degrees cooler than Phoenix.

Other scenic trips worth taking include venturing to: Prescott - site of the historic 1857 John C. Fremont House, the first territorial governor's mansion, and Whiskey Row; Apache Trail - a world-famous trail that twists through the Superstition Mountains and was once traveled by the Apache Indians; and Montezuma's Castle - a 12th-century Aztec-designed dwelling carved into a steep cliff, once inhabited by the Pueblo Indians.

These destinations can be reached in as a few hours by car from Phoenix.

ACTIVITIES: With so many sunshine-filled days, Phoenix is the perfect place to experience a range of outdoor activities. Horseback riding is a great way to see the spectacular Sonoran Desert, as is a rugged jeep ride. Spending an afternoon tubing or rafting the Verde or Salt rivers is another way to enjoy the outdoors. For the thrill seeker, a glider or hot-air balloon flight will take you high above the desert plateau and offer splendid views for miles.

Dependable sunshine and great weather make outdoor sports a way of life. Golf, tennis, hiking, mountain biking and in-line skating arepopular activities. Visitors can also choose from water skiing, sailing and fishing in the region's lakes and rivers.

DINING: Endless dining possibilities exist in Phoenix. With some of the world's best chefs, taste buds will be tantalized by indulging in a variety of foods including Fusion, Italian, Chinese, Mexican, Continental, Thai and Moroccan, just to name a few. It also is possible to taste a bit of the Old West by sampling a genuine cowboy mesquite-grilled steak at one of the many restaurants specializing in authentic Southwestern cuisine.

SHOPPING: When shopping you'll find a wonderful selection of upscale souvenirs such as beautifully handcrafted Native American turquoise jewelry and elegant leather goods. Everything from the latest in fashionable apparel to collectible artwork can be found at one of the many large shopping malls or tiny boutiques.

Sound like a great place for a conference? You bet! Plan to join us for E-Learn 2003, in Phoenix, Arizona, USA, November 7-11, 2003.

Membership Information • Conferences • Publications

Invitation to Join

The Association for the Advancement of Computing in Education (AACE) is an international, non-profit educational organization. The Association's purpose is to advance the knowledge, theory, and quality of teaching and learning at all levels with information technology. This purpose is accomplished through the encouragement of scholarly inquiry related to technology in education and the dissemination of research results and their applications through AACE sponsored publications, conferences, and other opportunities for professional growth.

AACE members have the opportunity to participate in topical and regional divisions/societies/chapters, high quality peer-reviewed publications, and conferences.

Join with fellow professionals from around the world to share knowledge and ideas on research, development, and applications in information technology and education. AACE's membership includes researchers, developers, and practitioners in schools, colleges, and universities; administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government with an interest in advancing knowledge and learning with information technology in education.

Membership Benefit Highlights

- *Gain professional recognition by participating in AACE sponsored international conferences*
- *Enhance your knowledge and professional skills through interaction with colleagues from around the world*
- *Learn from colleagues' research and studies by receiving AACE's well-respected journals and books*
- *Receive a subscription to the Professional Member periodical* Educational Technology Review [electronic]
- *Receive discounts on multiple journal subscriptions, conference registration fees, proceedings books & CD-ROMs*

Advancing Knowledge and Learning with Information Technology

BEST COPY AVAILABLE

AACE Journals

Abstracts for all journal issues are available at **www.aace.org/pubs**

Educational Technology Review – Electronic Journal

Educational Technology Review International Forum on Educational Technology Issues & Applications

AACE's member journal is the focal point to exchange information between disciplines, educational levels, and information technologies. Its purpose is to stimulate the growth of ideas and practical solutions which can contribute toward the improvement of education through information technology.

CITE – Electronic Journal

CITE CONTEMPORARY ISSUES IN TECHNOLOGY & TEACHER EDUCATION

An electronic publication of the Society for Information Technology and Teacher Education (SITE), established as a multimedia, interactive electronic counterpart of the *Journal of Technology and Teacher Education*.

International Journal on E-Learning

(formerly WebNet Journal & International Journal of Educational Telecommunications)

(IJEL) ISSN# 1537-2456 Quarterly

IJEL serves as a forum to facilitate the international exchange of information on the current theory, research, development, and practice of E-Learning in education and training. This journal is designed for researchers, developers and practitioners in schools, colleges, and universities, administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government.

Journal of Computers in Mathematics & Science Teaching

(JCMST) ISSN# 0731-9258 Quarterly

JCMST is the only periodical devoted specifically to using information technology in the teaching of mathematics and science. The *Journal* offers an in-depth forum for the exchange of information in the fields of science, mathematics, and computer science.

Journal of Educational Multimedia & Hypermedia

(JEMH) ISSN# 1055-8896 Quarterly

Designed to provide a multidisciplinary forum to present and discuss research, development and applications of multimedia and hypermedia in education. The main goal of the *Journal* is to contribute to the advancement of the theory and practice of learning and teaching using these powerful and promising technological tools that allow the integration of images, sound, text, and data.

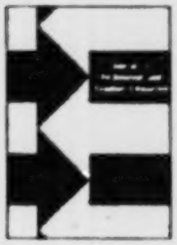
Journal of Interactive Learning Research

(JILR) ISSN# 1093-023X Quarterly

The *Journal's* published papers relate to the underlying theory, design, implementation, effectiveness, and impact on education and training of the following interactive learning environments: authoring systems, CALL, assessment systems, CBT, computer-mediated communications, collaborative learning, distributed learning environments, performance support systems, multimedia systems, simulations and games, intelligent agents on the Internet, intelligent tutoring systems, micro-worlds, and virtual reality-based learning systems.

Journal of Technology and Teacher Education

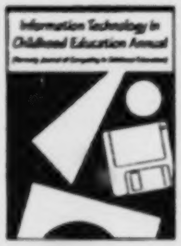
(JTATE) ISSN# 1059-7069 Quarterly



A forum for the exchange of knowledge about the use of information technology in teacher education. *Journal* content covers preservice and inservice teacher education, graduate programs in areas such as curriculum and instruction, educational administration, staff development, instructional technology, and educational computing.

Information Technology in Childhood Education Annual

(ITCE) ISSN# 1522-8185



A primary information source and forum to report the research and applications for using information technology in the education of children – early childhood, preschool, and elementary. The annual is a valuable resource for all educators who use computers with children.

BEST COPY AVAILABLE

AACE Conferences

Details for conferences are available at www.aace.org/conf

The exchange of ideas and experiences is essential to the advancement of the field and the professional growth of AACE members. AACE sponsors conferences each year where members learn about research, developments, and applications in their fields, have an opportunity to participate in papers, panels, poster/demonstrations and workshops, and meet invited speakers.

ED-MEDIA 2003

World Conference on
Educational Multimedia,
Hypermedia & Telecommunications

JUNE 23-28, 2003
HONOLULU,
HAWAII, USA

ED-MEDIA - World Conference on Educational Multimedia, Hypermedia & Telecommunications

This annual conference serves as a multidisciplinary forum for the discussion of the latest research, developments, and applications of multimedia, hypermedia, and telecommunications for all levels of education.

E-Learn 2003

World Conference on E-Learning in Corporate,
Government, Healthcare, & Higher Education

NOVEMBER 7-11, 2003
PHOENIX,
ARIZONA, USA

E-Learn 2003 - World Conference on E-Learning in Corporate, Government, Healthcare, & Higher Education

E-Learn is a respected, international conference enabling E-Learning researchers and practitioners in corporate, government, healthcare, and higher education to exchange information on research, development, and applications. This interdisciplinary dialogue is further supported by satellite events such as by the WebNet Symposium on the WWW and Internet.

SOCIETY FOR INFORMATION TECHNOLOGY & TEACHER EDUCATION 2003

14TH INTERNATIONAL CONFERENCE

MARCH 24-29, 2003
ALBUQUERQUE,
NEW MEXICO, USA

SITE - Society for Information Technology and Teacher Education International Conference

This conference, held annually, offers opportunities to share ideas and expertise on all topics related to the use of information technology in teacher education and instruction about information technology for all disciplines in preservice, inservice, and graduate teacher education.

Co-Sponsored Conferences

ICCE—International Conference on Computers in Education

ICCE is an annual event focusing on a broad spectrum of interdisciplinary research topics concerned with theories, technologies and practices of applying computers in education. It provides a forum for interchange among educators, cognitive and computer scientists, and practitioners throughout the world, especially from the Asia-Pacific region.

DECEMBER 3-6, 2002
AUCKLAND,
NEW ZEALAND

Membership Application

Preface

Welcome to E-Learn 2002 in exciting Montreal, Quebec, CANADA. The first E-Learn conference organized by the Association for the Advancement of Computing in Education (AACE) comes at an auspicious time. The past two years have been quite sobering for anyone interested in the topics encompassed in this inaugural E-Learn conference.

First, the downturn in the economy that began to affect North America two years ago (and even earlier in Asia and other parts of the world) has prompted many enterprises to take a hard look at their education and training initiatives, including those that might be described as e-learning, m-learning, virtual learning, Web-based learning, and so forth. As a result, these enterprises are, more than ever, looking to education and training programs as investments that must show a return.

Second, the shocking events of September 11, 2001, awoke many of us in North America and Europe to a vulnerability that others in less fortunate countries have lived with for decades. In the wake of these tragic events, managers and workers alike are considering e-learning in its many variants as an increasingly attractive alternative to traditional face-to-face education and training events that require people to travel great distances and/or be away from loved ones for long periods of time.

So what do the recent economic downturn and global terrorism have to do with E-Learn 2002? The answer is the importance of diverse professionals sharing research and development papers, tutorials, workshops, posters, demonstrations, panels, showcases and other events. E-Learn, like the other AACE conferences, is all about high quality research and development efforts. Unlike most commercial conferences, E-Learn presentations have been rigorously refereed by people who are the leaders in their respective fields. Thus, the quality of the sharing that goes on at this conference, and continues through the dissemination of these proceedings, becomes crucial to the realization of the return-on-investment we all seek, and the extension of learning and professional development opportunities beyond specific times and places.

In 2002, and in the wake of the aforementioned calamities, some might question the value of holding face-to-face conferences for which the submissions are due months in advance. After all, changes in technologies occur at an ever faster pace, and last month's cutting-edge development is sometimes this month's e-flop. Nevertheless, most of us recognize that as conference participants, we are not so much interested in technologies as ideas: ideas that are best shared, critiqued, and reshaped through personal dialogue and group discussion. While this could occur online, we recognize that many of the most important exchanges at conferences take place informally away from the formal sessions. Indeed, the face-to-face interactions are often the most valued and long-remembered aspects of any conference we attend, and we look forward to sharing these with you in Montreal.

E-Learn 2002 would not exist without the efforts of scores of volunteers, and so we would like to express our gratitude to the members of the Conference Steering and Program Committees as well as the local volunteers in Montreal who have made this event possible. Further appreciation is due to the highly professional staff at AACE who have worked tirelessly to ensure that this professional event is among the best of its kind. Finally, and most importantly, we wish to thank all of the researchers, developers, and others whose outstanding work is reported in these proceedings. Without you, there would be no quality to celebrate.

The more than 600 papers in this volume and on the accompanying CD-ROM come from contributors representing more than 50 countries. This is truly an international event. A year of preparation will soon be over, and E-Learn will be a pleasant memory. It is our hope that this memory will be refreshed each time you open this volume or access the conference CD-ROM, providing the wisdom and inspiration you seek. Further evidence of that living memory will be your continued participation in E-Learn conferences, and toward that end, we look forward to seeing you again next year at E-Learn 2003 in Phoenix, Arizona, USA; Nov. 7-11th (http://www.aace.org/conf/elearn).

E-Learn 2002 Program Chairs:
- Margaret Driscoll
IBM Mindspan Solutions, USA
- Thomas C. Reeves,
The University of Georgia, USA

TABLE OF CONTENTS

INVITED PAPERS

Be All That You Can Be—Again: E-Learning as a Means of Training Retiring Military to Become Teachers 2
Nancy Cassity Dunlap, Clemson University, USA
Creating and Maintaining Data-Driven Course Web Sites 9
Jesse M. Heines, University of Massachussetts Lowell, USA
Designing Authentic Activities for Web-based Courses 18
Jan Herrington, Edith Cowan University, Australia
E-Learning in Health Care - Policy, Practice, Evaluation, and Technical Implications - Emerging Trends 28
Penny Jennett, University of Calgary, Canada
eduSource: A Pan–Canadian Learning Object Repository 32
Rory McGreal, Athabasca University, Canada
Challenges in providing e-learning in the regulated pharmaceutical industry 41
James Vesper, Learnwright, Canada
The Open Source Movement, Publishing, and the Dissemination of Knowledge 47
Robert (Bob) F. Young, LuLu, Inc., USA

FULL PAPERS

Redesigning a Course Using an Analysis of Technical Problems Encountered in an Online Technology Training Course 53
Jason Abbitt, Mitchell Klett, Scott Graves, University of Idaho, USA
e-Learning and Knowledge Management: the MEMORAE project 61
Marie-Hélène Abel, Dominique Lenne, Omar Cissé, UMR CNRS 6599 Heudiasyc, France
Experimenting with Mobile Learning in a University Environment 67
Harri Alamaki, Radiolinja, Finland; Pauliina Seppala, Educational Centre for ICT, University of Helsinki, Finland
Instructional Models and Scenarios for an Open Learning Repository - Instructional Design and Metadata 75
Heidrun Allert, Learning Lab Lower Saxony, Germany; Hadhami Dhraief, Tobias Kunze, University of Hanover, Germany; Wolfgang Nejdl, Christoph Richter, Learning Lab Lower Saxony, Germany
Cognitive Styles and Medical Students' Learning 83
Zahra AlRawahi, Sultan Qaboos University, Oman
The Usability of the Virtual Hospital Round 91
Zahra AlRawahi, Saleh Shidhani, Sultan Qaboos University, Oman
Social Inclusion, Security and e-Democracy Issues in e-Government: the Role of e-Learning 98
Miguel Baptista Nunes, Maggie McPherson, Amy Whiteside, University of Sheffield, UK
Verifying Success in Distance Education 104
William Barber, Heather Clark, Elaine McIntyre, Appalachian State University, USA
Architecture of an E-Learning System with Embedded Authoring Support 110
Andreas Baudry, University of Hamburg, Dep. of Informatics, IMA Lab, Germany
Education Network of Ontario: Content/Curriculum Models for the Internet-connected Classroom 117
Mary Beam, Education Network of Ontario, Canada
The Changing Role of Instructors in Distance Education: Impact on Tool Support 123
Anke Biedebach, Birgit Bomsdorf, Gunter Schlageter, FernUniversität Hagen, Germany
Virtual University of Applied Sciences - German Flagship Projects in the Field of E-Learning in Higher Education 131
Michael Bischoff, Fachhochschule Lübeck, Germany

Delphi Study on Competency Model of Online Instructor 1778
insook lee, sejong university, Korea (South)
Time and Resource Issues Pertaining to the Design and the Management of Course Materials for a WebCT-Based Project with Engineering Students 1780
Geneviève Légaré, Concordia University, Canada
Teaching about Mythic Kings: How Integrating Multi-Media Presentation Technology with Traditional Essay Writing Has Helped Students Learn More History 1784
David Leinweber, Oxford College of Emory University, USA
Reusable Learning Objects: Hazards, Hi-Performance, and a New Convergence 1788
Juan Leon, Intelli-media, USA
An empirical investigation of student satisfaction with Web-based courses 1792
Peter Leong, Curtis Ho, University of Hawaii at Manoa, USA; Barbara Saromines-Ganne, Leeward Community College, USA

Implementing Library Instruction for Freshman Composition on WebCT: the Oakland University Experience 1796
Frank Lepkowski, Oakland University Library, USA
From the Global to the Local: New Policies for New Technologies 1799
Brian Lewis, Simon Fraser University, Canada; Jennifer Jenson, York University, Canada; Richard Smith, Simon Fraser University, Canada
Enabling open network access during exams 1803
Jeff Wright, Michael Chiles, John Paul, Luby Liao, University of San Diego, USA
Development of Web Server Surveilance Software 1807
Janet Light, Dept of ASCS, Canada
The Effect of E-mail Project on Enhancing EFL Learners' Academic Writing Skills 1810
Huifen Lin, Penn State University, USA
A Structured Approach to Program Expansion From On-Campus to Distance Delivery 1814
Marilyn Lockhart, Richard Howard, Larry Baker, Montana State University, USA
A Feedback Model And Successful E-Learning 1818
Helena Dedic, Steven Rosenfield, Vanier College & Concordia University, Canada; Yiping Lou, Louisiana State Universtiy, USA
The Development of a Web-Based Continuing Education Course for Camp Nurses 1822
Jo Lynne Lundy, Doctoral student - Nova Southeastern University, USA
E-learning pedagogy: The reveal of value adding learning processes. Definitions and Implications for dynamic learning content delivery 1826
Miltiadis Lytras, Athens University of Economics and Business, Greece
Community Action/interaction Management System (A Course/Group Management System that Fosters Community) 1831
Brian Mackie, Norbert Ziemer, Northern Illinois University, USA
A Perception of Next Generation E-Learning in Australia. 1835
Anthony Kadi, VENKATESH MAHADEVAN, Robin Braun, University of Technology, Sydney, Australia
Talk and Chalk Digital 1839
carmem maia, university anhembi morumbi, Brazil
E-Learning for Distance Learners — Does it work? 1843
John Mak, The Open University of Hong Kong, China
The use of Internet in a PBL course at ITESM 1847
Maria Magdalena Maldonado Avalos, Maria Magdalena Maldonado Avalos, ITESM, Mexico
A Distributed E-Learning Tool Based on Learning Objects 1851
Mauro Marinilli, Università di Roma Tre, Italy
Theoretical Framework: Towards a Grid for the Pedagogical Analysis of online courses 1855
Chomienne Martine, Cégep@distance, Canada
Supporting Elearning in Engineering Education 1859
Constantino Martins, Isabel Azevedo, ISEP-Instituto Superior de Engenharia do Porto, Portugal; Lígia Maria Ribeiro, FEUP - Faculdade de Engenharia da Universidade do Porto, Portugal; Carlos Vaz de Carvalho, ISEP-Instituto Superior de Engenharia do Porto, Portugal
Teaching Argumentation in Secondary School Through Computer Based and Face-to-face Debate 1862
Miika Marttunen, University of Jyväskylä, Finland
LLC Lecture Capture and Editing Tool for Online Course Delivery 1866
Masood Masoodian, Mark Apperley, Bill Rogers, University of Waikato, New Zealand
Supporting Online Meetings between Research Students and Supervisors 1870
Saturnino Luz, University of Dublin, Ireland; Masood Masoodian, University of Waikato, New Zealand
On-Demand Learning:Infrastructure Design and Managment 1874
Enid McCauley, Open Learning Agency, Canada
Technological Collaborations: Pairing Pre-service Teachers and Mentors 1876
Lillian McEnery, University of Houston- Clear Lake, USA
The Canadian Design Website: An Evaluation of Process and Product 1880
Laura April McEwen, Concordia University, Canada
Personality as a theoretical construct for the development of effective school leaders 1884
Michael McFrazier, Pamela Freeman, Prairie View A & M University, USA

Distance learning supports: The intentionality of pre-assessment surveys 1887
Patricia McGee, The University of Texas at San Antonio, USA
The Calibrated Course: Considering the Limits of Standards and Standardization 1891
Sylvia McLaurin, Georgia Center for Continuing Education, USA
Mobile what? The educational potential of mobile technologies. 1895
Thomas McManus, Saginaw Valley State University, USA
The Simulation Game: Discussing the educational potential of online multiplayer games. 1899
Thomas McManus, Saginaw Valley State University, USA
The Psychological Dimensions of Communities of Practice and their Relation to Online Learning 1903
Donald McMurray, Southern Cross University, Australia
WebQuests: Instructional and Design Techniques 1907
Donna McNierney, Youngstown State University, USA
Sustaining Instructional Design Strategies to Enhance e-Learning Among Learners 1911
Mustafa Md. Hanafiah, Open University Malaysia, Malaysia; Abtar Kaur, Open UNiversity Malaysia, Malaysia
A New Paradigm For OnLine Science Laboratory Learning Environments 1915
Gerald Meisner, LAAPhysics, USA
The Use of Course Mentoring Websites for Collaborative Curriculum Design and to Support Adjunct Faculty Teaching For Lesley University 1918
Dr. Linda Mensing Triplett, Lesley University, USA
Learning Cubes: A Model for Online Education 1921
William Messier, University of Macau, Macau
Public Relations Writing Moves From the Classroom On-Line: An Experience Report 1925
Alton Miller, Columbia College Chicago, USA
"Virtualizing": A Brazilian Initiative for Upgrading Media Knowledge of K-12 Public School Teachers 1929
Nilson Modro, LED UFSC, Brazil
Technological Applications in a Graduate Special Education Program 1933
Maribeth Montgomery Kasik, Governors State University, USA
CardioResearch: Supporting Knowledge Management in an Academic Cardiology Environment. 1936
Mariella Montoni, Catarina Rocha, COPPE Sistemas - Federal University of Rio de Janeiro, Brazil; Kathia Oliveira, Catholic University of Brasília, Brazil; Álvaro Rabelo Jr., Beatriz Salvador, Fundação Bahiana de Cardiologia (FBC), Brazil; Marcus Vinicius Souza, Ana Regina Rocha, COPPE Sistemas - Federal University of Rio de Janeiro, Brazil; Lisia Rabelo, Fundação Bahiana de Cardiologia (FBC), Brazil
Developing a 'WICeD' Team 1940
Peter Moodie, WICeD - The University of Waikato, New Zealand
Increasing Teacher Certification through a Multicampus(Blackboard) Praxis Network 1944
William Moore, Southern University, USA
Developing and Integrating Resources in a Virtual Learning Environment 1948
Raul Morales Salcedo, Tokushima University, Japan
The use of Virtual Learning Environments in UK Higher Education - Are VLEs supporting student-centred learning? 1952
Sue Moron-Garcia, Open University, UK
E-Learning & the Global Interface 1956
Michael R. (Mike) Mosher, Saginaw Valley State University, USA
Collaboration as a Response To Individualism in Distance Learning 1957
Robert Muffoletto, Appalachian State University, USA
E-Learning: "Self Service" Does Not Equal "Self-Directed" 1961
Felicity Mulgan, Content Alive Inc., Canada
Analysis of Students• f Eye Movement in Relation to Contents of Multimedia Lecture.........1965
Masayuki MURAKAMI, Kyoto University of Foreign Studies, Japan; Koh KAKUSHO, KyotoUniversity, Japan; Michihiko MINOH, Kyoto University, Japan
ON-LINE STUDENT SUPPORT SERVICES (OSSS) - A Pre-Testing Opinion Survey of Distance Learners on OSSS 1969
Kantayapalem Murali Manohar, Kakatiya University, India

Internet-based Distance Learning in Slovakia 1973

"Be All That You Can Be"--Again
South Carolina Troops-to-Teachers Coalition Alternative Route to Teacher Certification ("T^3 ARC")

Nancy Cassity Dunlap
Associate Director, School of Education
Clemson University
USA
Ndunlap@clemson.edu

Abstract: The South Carolina T^3 Coalition has designed this alternative to provide requisite training and credentialing for retiring military personnel to become teachers in the schools most in need. Incorporating a unique blend of on-line instruction and hands-on practical experiences, the program is accessible around the clock and around the world. Participants may begin training within two years of retirement, and, through special Proviso by the state legislature, they will be classified as resident students at the four partner universities. The curriculum, grounded in a documentable knowledge base, reflects what a new, second-career professional needs to know and be able to do to become a successful teacher. Featuring a robust curriculum, a powerful e-learning delivery mode, a strong research/evaluation component, a year-long paid internship, and two years of follow-up with skilled mentor teachers, this program has the capacity for ameliorating the teacher shortage in South Carolina and elsewhere.

"What teachers know and can do is the most important influence on what students learn," *What Matters Most*, a report of the National Commission on Teaching and America's Future, 1996.

Introduction

Master Sergeant Virginia Dukes grew up in Newark, the only child of a single parent living in the inner city. The Army offered her an escape from her bleak surroundings and promises of opportunity, which she took. She completed her education, had an illustrious career in training and data management, and is retiring, but at 39, she is a vital, energetic, bright, and motivated woman who feels that teaching might be a viable option for her. She also wants to locate in the Sunbelt, and has chosen to live in South Carolina.

Lt. Col. Raoul Hernandez and Maj. Donna Hansen met while both were stationed at the Beaufort Air Station. They married, raised a family, and after successful careers in the Marine Corps (she in public information, he a Provost Marshal), have decided to return to the Beaufort area. She has her degree in Journalism from the University of Montana; he received his JD degree from George Washington University. They have a desire to give back to the community, and are considering teaching as a second career.

Commander Mercer Jamison was born and raised in Pocataligo, SC, a small crossroads in the South Carolina Lowcountry. A young African-American with few local prospects, he couldn't wait to get away, and when a Navy recruiter offered him a chance to see the world and complete his education, he jumped at the chance. Now, 25 years later, with a bachelor's degree in engineering from Old Dominion University and 15 years as a nuclear engineer, he is preparing to retire and is anxious to return home, where he hopes to make a difference for rural youth. He wants to become a teacher.

The players in these three fictitious scenarios have several things in common: all have had successful careers as military commissioned or non-commissioned officers; all want to come to South Carolina; all want to teach; all are attempting to begin a new chapter of their lives; and all bring a abundance of talents and skills and a world view to an area and a career field that desperately needs them.

BEST COPY AVAILABLE

However, traditional programs would require up to two years to complete after the service member leaves active duty, and they would forego a paycheck during training. Also, if they were in traditional teacher-preparation programs, their maturity, experience, expertise, and training would not necessarily be valued. Or, as in some alternative-certification programs, they would be placed in the classroom with no preparation or supervision and left to their own devices to survive (or not) in the school setting.

To be successful, aspiring teachers need more than a textbook and a handshake. They need training--not a traditional undergraduate teacher-training program (although those options continue to be available), but one tailored specifically for them, to provide necessary knowledge and skills, to provide options for demonstration of proficiency, to avail them of what they need to be successful in this social structure called "school," while acknowledging the talents, experience, and expertise that they bring with them. The training also needs to be readily accessible, and it should enable military personnel to assume a teaching position immediately upon exiting their military careers, but with continued follow up, training, mentors, and supervision—all focused upon the new teachers' success.

The South Carolina Troops-to-Teachers (T^3) Coalition has developed a program using "blended learning" (e-learning and practical, hands-on field experiences) to enable these folks to realize their dreams while concurrently ameliorating the teacher-shortage needs in South Carolina--the needs for specific content areas, in grade levels, in small, rural, or inner-city schools, for minority representation, and for male teachers.

The South Carolina Troops-to-Teachers Coalition consists of four institutions, five agencies, and a corporate partner: Clemson University, the University of South Carolina, the Citadel, and South Carolina State University have come together with five agencies (the Governor's Office, the South Carolina Center for Teacher Recruitment, the Commission on Higher Education, the Employment Security Commission, and the State Department of Education) and IBM/Lotus to craft an initiative to enable commissioned and non-commissioned officers with college degrees to secure the requisite training and credentialing to become teachers.

The target group consists of members of the armed forces, commissioned or non-commissioned officers, who possess a bachelor's degree or higher.

The reasons to tap this talented pool are numerous:

1. The military began downsizing in 1994, sending well-qualified personnel into the civilian work force.
2. Military personnel often have strong content skills, particularly in math and science.
3. Commissioned and non-commissioned officers possess high levels of training and education; indeed, many have master's degrees.
4. The potential pool is great; while the military is not presently downsizing, many active-duty personnel are making plans for retirement–often wanting to return "home."
5. Within the ranks exists a high ethnic minority ratio; this will enable us to recruit, train, and place heretofore under-represented minorities.
6. Likewise, there is a high ratio of males; this cadre can provide more men for the classrooms.
7. Their military experience as trainers; provides them with a solid foundation for a teaching career; all commissioned and non-commissioned officers have served in various training capacities during their careers.
8. They have the added benefit of being trained in providing safe and secure environments; this is an added benefit for school safety and violence prevention.
9. In their military careers, they have gained organizational, interpersonal, technical, technology, and leadership skills.
10. They are great role models for kids--mature, drug-free, and physically fit.
11. Finally, they bring a wealth of personal and professional experiences and a world view heretofore missing in our schools.

Because of their high degree of training and education acquired during their military service, because the number of teachers who can be trained from this pool is potentially much greater than many sources, and because of the high ethnic minority and gender ratios which could significantly ameliorate under-representation of ethnic minorities and men in these critical-needs areas of education, this group would be a benefit to and a resource for South Carolina's schools and our young people.

Evolution of T^3 ARC

The T^3 ARC began in August 1999; the first year was dedicated to planning. With a small grant, the Coalition has undergone a rigorous process to design an alternative certification program to allow participants to complete their requisite course work while still on active duty using e-learning and blended-learning strategies.

The Coalition reviewed the existing literature on alternative certification, best practice, and research, to examine the programs of other states, teacher education programs, and other entities. While most states have developed or are developing routes for alternative licensure, none possesses the uniqueness of the proposed South Carolina model.

Based on the premise posited in *What Matters Most*, a report of the National Commission on Teaching and America's Future, *"What teachers know and can do is the most important influence on what students learn,"* the Coalition began by processing ten essential questions:

1. What do mature, new, second-career teachers need to know? Can we defend this through a scientifically documentable knowledge base?
2. What do mature, new, second-career teachers need to be able to do? Can we defend this through a scientifically documentable knowledge base?
3. What specific competencies do they need?
4. What specific competencies do they possess and can they demonstrate?
5. How do we identify these competencies?
6. How do we identify gaps?
7. Can we develop a training model based on this gap analysis?
8. What will it include?
9. How can we deliver it? Can we deliver via the Internet?
10. What resources (human, material, technological) do we need to do this?

Upon completion of this analysis, the Coalition then reviewed standards, best practice, knowledge bases, and research from the following agencies and organizations:

National Board for Professional Teaching Standards (NBPTS)
National Association for Accreditation of Teacher Education (NCATE)
Council of Chief State School Officers (CCSSO)
Interstate New Teacher Assessment and Support Consortium (INTASC)
Key Competencies (Australia)
Teachers College, Columbia University
National Commission on Teaching and America's Future (*What Matters Most*)
Renaissance Group
University of Arkansas Profile of a Beginning Teacher
American Association of State Colleges and Universities (AASCU)
Educational Testing Service (PRAXIS)
American Association of Colleges of Teacher Education (AACTE)
Holmes Partnership
National Network for Educational Renewal (NNER)
Carnegie Foundation for the Advancement of Teaching
South Carolina's Assisting, Developing, and Evaluating Professional Teaching (ADEPT)
Good Teaching Matters; a Report of The Education Trust
Conceptual Frameworks of the partner universities
American Council on Education

The Coalition also adopted the following "touchstones" to guide the process and to keep the group on-track and on-target:

> "Develop high-quality pathways to teaching for recent graduates, mid-career changers, paraprofessionals already in the classroom, and military and government retirees." –National Commission on Teaching & America's Future, *What Matters Most*, Recommendation 3
>
> "The fundamental differences between an alternative and traditional program are the target audience, the training design, and the length of training, not the program content, rigor, or expected outcomes." --AACTE, *Alternative Preparation for Licensure: Policy Statement*

"To do and perform all things necessary to encourage, uphold, and dignify the profession of teaching." --*Carnegie Foundation for the Advancement of Teaching and Learning*
The Coalition would return to these touchstones often.

The Curriculum

Upon examination of the standards and evidence, the Coalition developed two documents: (1) What teachers need to know and (2) what teachers need to be able to do. To achieve the necessary validation, these lists were widely circulated within and without South Carolina; teachers, teacher educators, parents, business people, community leaders, and the Military Assistance Council, the advisory group for the Coalition, had the opportunity for input. It was important that this be as comprehensive, as valid, and as reliable as possible.

The result is a rich, valid, robust curriculum, grounded in best practice and research, based upon what career-changing professionals need to know and be able to do to become successful teachers, (acknowledging that pedagogy for a 40-year-old professional should differ from that for a 20-year-old college sophomore AND recognizing the vast expertise and experience that military professionals bring to the profession) in nine discrete modules divided into three blocks, from the more general and theoretical to the more specific and concrete:

Block One
- ☐ Psychological Foundations of Adolescent Learning and Development
- ☐ Technology in the Classroom
- ☐ Cultural Distinctions and Diversity

Block Two
- ☐ Community Resources
- ☐ Application of Research
- ☐ Student Assessment and Evaluation

Block Three
- ☐ Methods and Strategies (content-specific in mathematics, sciences, and English/language arts)
- ☐ Classroom Organization and Management
- ☐ The Culture that is School

The Technology

The group then, upon returning to the "Ten Questions," determined that we could, indeed, take this list of what teachers need to know and, using a "gap analysis," could tailor an individualized, performance-based, open-entry program based upon the client's documented experiences and expertise, over the World-wide Web, using state-of-the-art technology and synchronous and asynchronous delivery of modules rather than traditional graduate-level courses.

From this point, we turned to the technology experts; upon reflection, it was determined that we needed a vehicle not only of getting the courses on-line, but also a means of managing variable credit, generating student transcripts, providing means of interactivity between faculty and participants, among other significant issues, and an in-depth review of technological potential yielded two likely candidates: IKON Technologies and IBM/Lotus. IBM/Lotus remains as a partner in crafting the technological methodology for on-line delivery and management of this complex project. (Due to corporate redirection, IKON is no longer a partner). The support and engagement of IBM/Lotus has been exemplary; not only is their LearningSpace a robust system, but their technical support has been exceptional.

The Academic Program

Military personnel may access the program during their last two years of active duty through the T^3 ARC Website (http://www.hehd.clemson.edu/TTT/). Since all of these folks will have bachelor's degrees (and many will come with master's degrees), content expertise is presumed; however, prior to admission into the program, the candidate must provide passing scores from the Praxis II subject-area examination to validate currency of content knowledge. The candidate's program will be determined based upon what experiences he/she can validate from the military. University faculty will provide the personalization.

The participant will have the modules available around the clock; the professors will maintain maximum availability. Options will be available, also, for real-time discussions, chat rooms, white boards, and the like.

Additionally, since teacher education cannot occur in a vacuum, field experiences and practical applications of skills are built into each module. The experiences are as varied as the curriculum, but are a requisite part of the training, hence the "blended-learning" methodology that complements e-learning.

Also, the Coalition has designed a schedule to allow the participant to work on as many as three modules in an eleven-week period. If deployed to a combat zone, however, the "clock stops," and he or she may resume the module at the point at which he/she left it. The academic schedule of courses is presently designed through 2008, and it takes into account holidays and other pertinent issues; the university Registrar has incorporated the [essentially quarter] schedule into its semester-based calendar, thus allowing for acceleration of participants through the program. All of the support mechanisms are in place.

Upon completion of the modules, the participant will be placed in a one-year internship, during which he/she will not only undergo induction, as does any first-year teacher, but he/she will have to demonstrate the knowledge gained through the modules–the "What teachers need to be able to do" list. Resources will be made available to provide for mentor teachers and other resources necessary to assure candidate success. Accompanying this internship is a year-long seminar (also carrying academic credit), bringing together participants from the four regions with university faculty, school district and school personnel, and other pertinent, relevant resources.

The Placements

The Coalition determined four criteria for placements as critical:

1. Districts "in greatest need of technical assistance;"
2. Geographic critical teaching needs, based on criteria and annual determination of the State Board of Education;
3. Top 12% in the State for high school dropouts;
4. Proximity to military installation; must be either inner-city or rural and must meet federal poverty guidelines for "high need LEAs"

Based upon recent information from the State Board of Education regarding geographic critical needs, the Coalition has identified 78 schools throughout the state that meet one or more of the above criteria; this will likely change as new data become available.

The Coalition has determined four areas of the state; each of the partner universities will have responsibility for monitoring the internship and two subsequent years of follow up. Subsequent monitoring and support for this three-year program will be provided in partnership among the Coalition, the LEA, and the partner university. Additionally, we will gather data on successful program completion, internship, and ultimate placement within the schools and districts most in need.

Project Uniqueness

The program is unique in many ways; following is a compendium of reasons:

Participants may begin within two years of separation from military service;

Participants may participate at their duty station, anywhere in the world;

Program uses state-of-the-art technology;

Participants are provided a waiver of out-of-state tuition (Section 5A.32 of the 2002 Budget Bill, SC General Assembly);

Participants partake of a robust curriculum designed to prepare them for the realities of the classroom;

Coordination among 4 universities and 5 agencies, school districts, and a corporate partner; over 90 people have been involved in the genesis of this project, including university faculty, corporate officers, technicians, university administrators, school district personnel, military representatives, and agency staff;

Field experiences and practical application of skills are incorporated into every course;
Curriculum developed by university faculty based on what teachers need to know and be able to do;
Graduate-credit modules via Internet delivery with synchronous and asynchronous options;
One-year paid internship with skilled mentor teacher; participants will not miss a paycheck;
Placement in districts with greatest need;
Strong research/evaluation component;
Focus on retiring military with bachelor's degree or higher;
Program availability year-round, with course rotation;
Flexibility:
  Participant may "stop the clock" and resume at a later date;
  Program will be available around the clock, seven days per week;
The result is a program that is research-based, facile to use and to navigate, easy to access, is valid, is reliable, and is grounded in reality and a scientifically documentable knowledge base.

Lessons Learned

Throughout the development and implementation activities, the Coalition learned many lessons as we blazed new trails through the *Terra Incognito* of e-learning and blended learning. One of the most compelling was to identify, analyze, and document our processes as we proceeded. Following is a listing of some of the processes and some samples within each; of course, different projects will render differing processes.

Table 1: PROCESS ANALYSIS

Conceptual processes
Idea, needs assessments, literature searches

Analytical processes
Data, resources, best practice, research

Academic processes
Curriculum development, committees, materials selection

Political processes
Funding, support, consensus, residency

Marketing processes
Advertising, web site, monitoring, print media

Documentation processes
Data collection/analysis, participation, support

Fiscal processes
Grants, finances, resources

Implementation processes
Hardware, software, enrollments, fees

Continuous Improvement processes
Growth plans, adjustments, evaluation, realignment

Suggestions from the Trenches

Determine needs--yours and "theirs," whoever "they" happen to be. Nurturing partnerships is critical to the success of any collaboration. In every case, the partners have institutional goals and needs to meet; likewise the representatives of the partnership may have personal and/or professional goals for his/her participation (research, publications, *et alia*). Partnerships like the Coalition require nurturing to maintain a high level of effectiveness.

Review the literature--research, best practice, state-of-the-art, et alia. Scholars begin their work with an in-depth review of what is happening in the field they are researching; they read, review, analyze, and reflect on the work that has been done and in the areas that they are studying. Likewise, with this project, we located, through traditional and non-traditional means, the scope of the body of work in the field. What we discovered was interesting; while there was an abundance of descriptive pieces ("what we did;" "how we did it"), for example, there were very few research studies looking at the long-range efficacy of alternative programs. This provided us with another unique niche; we will be gathering and analyzing data for a long-term study of our program compared to other non-traditional as well as traditional teacher-preparation programs. This exercise also established the uniqueness of our project. There was clearly nothing else like it.

Build and nurture coalitions. It is critical to bring the appropriate parties to the table early in the process so that they have ownership within their organizations. Coalitions do not happen by accident; they are carefully nurtured and evolved. Care must be exercised, however, to avoid the evolution of factions; one way to avoid this is to work toward achieving consensus rather than majority votes.

Determine and analyze data. "Prove it," the naysayers will demand; "show me the data," potential funders will insist. You must be able to determine what kinds of data to collect and what you plan to do with the data. For example, we will want to know how our T^3 ARC participants compare to other first-year and fifth-year teachers from other alternative programs, so we must determine whether to use standardized test scores--how many pass on the first attempt, for example--in keeping with our research and evaluation design.

Continually review and adjust. Sometimes, something just will not work; do not fret over it or mourn it; adjust and learn from it. There will be divergences; there always are for pioneers. Lewis and Clark knew where they were going, but they were continually surprised along the way. Likewise, program developers need to enjoy the sights along the trail as they blaze it, but they need to be able to retrack and change direction when they hit the big water.

Engage stakeholders in processes. Who are your stakeholders? Are they policy makers? Are they private business/industry leaders? The determination of where and when a project needs outside support may mean the difference between success and failure. Bring them to the table early and enlist their endorsement; letters of support are always helpful. And make sure that they receive periodic updates of progress.

Build capacity. The intent is to create synergy—to create an effect that no partner can achieve alone; therefore, the whole becomes greater than the sum of the individual parts. But the results can be thrilling!

Document! Document! Document! Enough said.

Finally, enjoy the adventure of discovery! According to Lester Thurow (1996), "With similar persistence [to Lewis and Clark] and willingness to attempt the unknown, let our journey begin!"

Finis

Military personnel represent a wealth of talent, experience, diversity, knowledge, expertise, skills, and world views; they are grounded in the content areas, and many have extensive training experience. What opportunities exist to install this leadership and talent in the inner-city and rural schools most in need! And our new cadre of teachers can "be all that they can be," yet again.

Creating and Maintaining Data-Driven Course Web Sites

Jesse M. Heines
Department of Computer Science
University of Massachusetts Lowell
United States
heines@cs.uml.edu

Abstract: This paper deals with techniques for reducing the amount of work that needs to be redone each semester when one prepares an existing course Web site for a new class. The key concept is algorithmic generation of common page elements while still allowing full control over page content via WYSIWYG tools like Microsoft FrontPage and Macromedia Dreamweaver. The paper explores both client- and server-side techniques and discusses their advantages and disadvantages. The most advanced techniques are those that encode control information in XML rather than HTML or JavaScript and apply that information on the server side using XSL and JavaServer Pages. The paper also touches on course organization techniques that might involve students in the creation and maintenance of course Web sites, thereby fostering more student-centered learning.

Itsa Lotta Work!

Numerous student and faculty surveys have shown that parties on both sides of the podium consistently laud the instructional benefits of course Web sites. For example, when 62 students in a Web site-supported course were asked to react to the statement "I wish other professors maintained course Web sites like this one," 82.3% "strongly agreed" and another 16.1% "agreed" (Heines 2000). On the faculty side, 68.0% of the 25 respondents to a survey on course Web site development who did *not* have a course Web site (out of 150 total responses) indicated that they would like to have one (Grankovska & Heines 2002). Gehringer (2002) found that while only 7.6% of 250 survey respondents reported that their universities have a policy on making course materials publicly available on the Web, 85.2% at least posted their syllabi, 68.8% posted their assignments, and 53.2% posted their lecture notes.

There is also ample evidence that the amount of work it takes to post material on the Web is considerable. David Jordan (1997) estimated that "creating and maintaining the site roughly doubles the work involved in teaching the course." Even with the availability of commercial tools, 81.3% of the 150 professors who responded to the Grankovska and Heines survey (2002) cited time as the most "serious obstacle to making their course Web site everything they want it to be" or the most "significant part of the reason why they did not have a course Web site."

Even with commercial tools – general-purpose as well as those designed for instructional use – course Web site development is time-consuming at best and daunting at worst. But as difficult as *creating* a rich course Web site may be, *maintaining* it – keeping its content and links current and updating the site when the course is revised – is even more arduous. Even for those of us who are highly dedicated and have the best of intentions, the amount of work that seems to need to be redone each semester is so frustrating that we often give up and leave things the way they were. The focus of this research is therefore to explore techniques for reducing the amount of work needed not only to create course Web sites, but to maintain them as well.

Moving to Data-Driven Course Web Sites

There are two basic ways to build most computer applications. First, you can embed data within program code, a technique referred to as "hard-coding." On a Web site, this is analogous to creating pages in HTML, either directly using a text editor and entering HTML tags and attributes yourself, or indirectly using a

WYSIWYG editor like Microsoft FrontPage or Macromedia Dreamweaver that creates those tags and attributes for you. Pages can be built from templates to achieve consistency in their look and feel, but, for the most part, once a hard-coded page is created it remains independent of all other pages on the site.

The second approach is to separate content data from code logic and thereby make the application "data driven." On a Web site, this is analogous to creating pages where what is displayed is stored in some sort of data file, while how that content is displayed is controlled by some sort of scripting technique such as JavaScript on the client side or JavaServer Pages on the server side. Overall look-and-feel or deployment of a new feature across the entire site can then be modified or added by manipulating a small set of control files.

Data-driven techniques are used by virtually all commercial course Web site "engines" such as Blackboard (http://www.blackboard.com), WebCT (http://www.webct.com), and IntraLearn (http://www.intralearn. com). Such tools are excellent for courses that fit their models and instructors who are satisfied with their facilities, but it is typically difficult to break out of their paradigms to add new course models or interaction capabilities. While this restriction is frustrating to experienced Web developers, the data-driven characteristics of these engines use techniques that all serious developers embrace.

Consider, for example, the elements in the typical lecture notes posting for shown in Figure 1. Focusing solely on the notes themselves inside the navigation frames, you can see that there are numerous common elements here that will be formatted identically on all lecture notes pages: the course number, class number, and date in the header, as well as the eight control buttons to the right of the "Handouts and Materials" heading. From left to right, the four arrow buttons jump to the first, previous, next, and last posted lecture notes. Likewise, the four control buttons jump to the course home page, print and reload the current frame, and remove (or restore) the navigation frames. It is probably obvious that you wouldn't want to include the code needed for each of these elements on every lecture notes page. It is more subtle, however, to appreciate that the "previous" and "next" page is different for every page and therefore requires that link to be generated algorithmically rather than hard-coded. If you have the dates of each class stored in some sort of data structure, you can not only write code to format the header information consistently across all similar pages, but you can also automatically generate the links from one page to the next.

Using JavaScript on the Client Side

There are two basic choices for implementing data-driven course Web sites on the client side: Java applets and Dynamic HTML. The use of Java applets and similar plug-ins (like Macromedia Flash) involves a dramatic shift away from the basic programming paradigm based on HTML that is used in most WYSIWYG editors. This is not inherently bad, and many would argue that it's high time we retired HTML anyway. However, use of Java applets obviously requires knowledge of those languages and their facilities that is considerably beyond the scope of this paper.

Dynamic HTML, on the other hand, is easily integrated into standard Web pages in the form of JavaScript or VBScript. There is no need to throw away HTML that you've already generated. Instead, you can simply augment it by inserting scripting code into the same file. VBScript is a Microsoft product and is more closely integrated with Internet Explorer than JavaScript (or even Jscript, Microsoft's version of JavaScript), but I prefer to work in JavaScript because it is more universal. There are differences in the way JavaScript works on the major browsers, but those differences tend to be small and easy to rectify.

The common elements in Figure 1 pointed out in the previous paragraph are all implemented on my Web site using JavaScript. I use a couple of simple conventions to make the job easier, which help me organize the site as well as make it data driven. First, I name all related files sequentially, like class01.htm, class 02.htm, etc. Thus the file name indicates which class it is, and I can move content between files at will without affecting the links between them. (I do this all the time, because no class ever goes exactly as planned.) This simple convention makes it possible to determine the class number dynamically using the JavaScript code shown in Listing 1. When this code is included in an HTML page – or, as I implement it, in a common file that is included via a link in almost every HTML page on my site – it sets variables that can be used to generate the page header and to control navigation between related pages "on the fly." For example, the page shown in Figure 1 has a URL of http://www.cs.uml.edu/~heines/91.353/91.353-2001-02s/353-lecs/class09.htm. Executing the routine in Listing 1 from this page sets variable `intClassNo` to 9 and `strPrefix` to `"class"`.

Technical Lecture Notes

Introduction to JavaScript — CWP Ch. 24 — continued

Basic statements

- `document.write` and `document.writeln`
- embedding HTML in output strings
- using single and double quotes and escaping characters
- using method `window.alert(...)`, especially for debugging
- setting the `window.status` property
- using variables
    - the `var` statement — no declared types!
        - use Hungarian notation
        - first 1-4 characters represent the data type
        - examples: `str`, `n` or `int`, `arr`, plus prefixes for various object types
    - but there really are types internally! therefore you need a few tricks to do type conversion...
        - using "" to force string types
        - function `parseInt` to convert a string read from a field to an integer so it can be used in calculations
        - to convert a number to a string, just concatenate ""

Figure 1: A typical Web posting of lecture notes with numerous common page elements.
The vertical button labels were added for clarity; they do not appear on the actual Web page.

Listing 1: JavaScript code to extract the 2-digit lecture number and its prefix from a file name.

```
// determine the file name from the current page's URL
var strURL = "" + document.location ;         // full URL of current page as a string
var intSlashPos = strURL.lastIndexOf( "/" ) ; // position of last forward slash in URL
var strFile =                                 // name of lecture notes file
        strURL.substr( intSlashPos+1, strURL.length ) ;

// extract the class number and its string prefix
var intDotPos = strFile.lastIndexOf( "." ) ;  // position of dot in filename.extension
var strClassNo =                              // 2-digit class number as a string
        strFile.substring( intDotPos-2, intDotPos ) ;
if ( strClassNo.substring( 0, 1 ) == "0" )    // remove leading 0 if it exists
  strClassNo = strClassNo.substring( 1, 2 ) ;
var intClassNo = parseInt( strClassNo ) ;     // class number as an integer
var strPrefix =                               // characters in file name that precede
        strFile.substring( 0, intDotPos-2 ) ; //    the class number
```

BEST COPY AVAILABLE

Next, I use a simple JavaScript array data structure to hold the dates of all classes. The second convention involves the format in which those dates are stored: YYYY-MM-DD, known as "ISO 8601" format because it is an official standard of the International Organization for Standardization. The advantage of ISO 8601 over the more common M/D/YY format used in the United States is not only that it is Y2K compliant, but, more important, that it allows dates to be sorted alphanumerically. Thus my array looks like this:

```
// class days for the Spring 2002 semester
var arrClassDate = new Array(
        "2003-01-23" ,  //  1
        "2003-01-30" ,  //  2
        "2003-02-06" ,  //  3
           . . . and so on . . .
        // "2003-05-01" ,  // 13
        // "2003-05-08" ,  // 14
        null ) ;
```

If the lecture notes for a certain date have not yet been posted, or if I simply don't want to make them available to students yet, I comment out the corresponding dates in the array as you see for May 1 and 8 above.

Given a series of lecture notes files that follow the naming convention discussed above and their corresponding dates in an array data structure, I use the built-in JavaScript Date object along with a few small routines of my own convert the ISO 8601 string to the "Weekday, Month Day, Year" format you saw in Figure 1. (All of these routines are available from the author on request.) In addition, I use the same data to dynamically create the links for the four arrow buttons. Part of the code accomplishes this is shown in Listing 2 to give you a feel for what's involved. Data-driven creation of these links insures that they will never be "broken," and that, for example, the "Next" and "Last" buttons are automatically disabled when students are viewing the last page in the sequence.

Listing 2: JavaScript code to generate the previous and next page buttons.

```
/** output links to first, previous, next, and last pages
 *  @param intClassNo an integer specifying the current page number
 */
function setPrevNextLinks( intClassNo )
{
  // last and next buttons
  if ( arrClassDate[intClassNo] != null )
  {   // enabled versions
    document.writeln(      // strImagesLoc is the relative path to the images directory
      '<a href="' + strPrefix +
      ( arrClassDate.length-1 < 10 ? '0' + (arrClassDate.length-1)
                                   : (arrClassDate.length-1) ) + '.htm">' +
      '<img src="' + strImagesLoc + '/blue_last.gif" alt="Go to Last Lecture Posted" '+
      'align="right" border="1" hspace="2" width="24" height="24" ' +
      'onMouseDown="this.src=\'' + strImagesLoc + '/blue_last_down.gif\'" ' +
      'onMouseOut="this.src=\'' + strImagesLoc + '/blue_last.gif\'"></a>' ) ;
    document.writeln(
      '<a href="' + strPrefix +
      ( intClassNo+1 < 10 ? '0' + (intClassNo+1) : (intClassNo+1) ) + '.htm">' +
      '<img src="' + strImagesLoc + '/blue_next.gif" alt="Go to Next Lecture" ' +
      'align="right" border="1" hspace="2" width="24" height="24" ' +
      'onMouseDown="this.src=\'' + strImagesLoc + '/blue_next_down.gif\'" ' +
      'onMouseOut="this.src=\'' + strImagesLoc + '/blue_next.gif\'"></a>' ) ;
  }
  else
  {   // disabled versions
    document.writeln(
      '<img src="' + strImagesLoc + '/blue_last_disabled.gif" ' +
      'align="right" border="1" hspace="2" width="24" height="24">' ) ;
    document.writeln(
      '<img src="' + strImagesLoc + '/blue_next_disabled.gif" ' +
      'align="right" border="1" hspace="2" width="24" height="24">' ) ;
  }
  . . . code for the first and previous buttons is analogous to what appears above . . .
}
```

Moving to XML

The use of JavaScript and its built-in structures work very well for simple data-driven routines that use Dynamic HTML. Development is straightforward, code size is small, testing is easy, and client-side execution is fast. When the data gets more complex, however, arrays and JavaScript's simplified class structure (some would call it a "pseudo class structure") are insufficient to encapsulate the relationships between various data elements and make them available throughout the Web site. A better alternative is to encode data in XML, the eXtensible Mark-up Language, and access it using one of the various techniques specifically developed to allow XML data to be used on Web pages.

For readers unfamiliar with XML, one can describe it in a nutshell as a data-encoding scheme in which HTML-like tags are used to label individual data items. Those items can then be arranged into a hierarchy that structures the entire data set and adds further meaning (semantic content) to its components. The simple, self-explanatory example shown in Listing 3 should suffice to give a feel for how data is encoded in XML. Given such data, it is not difficult to imagine using this information in a variety of displays, such as:

- a listing of all sessions sorted by the primary presenter's last name
- a listing grouped by the various application domains, technologies, or strategic-focuses
- an APA-formatted bibliographic reference or one in any other standard format

Listing 3: Sample XML file to show basic syntax and structure.

A full discussion of XML is, of course, beyond the scope of this paper, but many books are available that address its syntax, capabilities, and related technologies (of which there are many). My favorite remains Martin (2000), even though it is now two years old (ancient in this field!).

There are several ways to work with XML data, the easiest of which may be via client-side extensions to HTML provided by Microsoft in Internet Explorer 6.0 and available as a plug-in to Internet Exploror 5.5. This client-side technique is unique to Internet Explorer, however, and therefore is not truly usable in course Web sites that may be accessed via other browsers or even versions of Internet Explorer older than 5.5. Thus the preferred way to use XML is on the server side.

XML parsers come in various flavors, many of which are freely available (a list of reasonable size is available at http://www.w3.org/XML/#software, W3C 2002a). Most XML parsers can be seamlessly integrated with other server-side techniques, although the effort to do so can be substantial due to inadequate and sometimes even incorrect documentation. Parsers exist that work with CGI programs written in C++ or Perl, as well as Java programs implemented as JavaServer Pages or Java Servlets. Some parsers, such as *Xerces* from the Apache Software Foundation (2002), load entire XML documents into memory and allow them to be manipulated using a Document Object Model (DOM). Others, such as the *Simple Application Programmer Interface (API) for XML* (SAX), read XML data as a stream and process each data node in turn (Meggison 2002). I prefer to process XML data using XSL – the *XML Stylesheet Language* – which has a built-in parser and capabilities specifically designed to translate XML data into a variety of formats, including HTML (W3C 2002b, Heines 2003). Listing 4 shows an XSL file that generates the output shown in Figure 2 from the XML data in Listing 3.

Heines, Jesse M. *Creating and Maintaining Data-Driven Course Web Sites.*

Figure 2: Output generated by applying the XSL file in Listing 4 to the XML data in Listing 3.
minimum.jsp is a JavaServer Page that applies XSL to XML and is available from the author on request.

The advantage of using these techniques on the server side is that it is possible to know exactly what software is installed on the server and thus not have to deal with browser differences on the client side. XSL stylesheets (as well as programs that process XML using the DOM or SAX) use the XML data to generate straight HTML with is then "sent down the pipe" to the client. That HTML can be as simple or as sophisticated

BEST COPY AVAILABLE

as you like, including embedded code that detects and compensates for the minor differences between browsers at the HTML level. Luckily, as of this writing those differences are small.

Note that all of these techniques require some degree of server-side programming support, something that is not always enabled on university servers. In the UMass Lowell Computer Science Department, for example, we do not allow server-side scripts of any sort on our main server that hosts student and faculty Web pages due to the high probability that such scripts will crash the server. As an alternative, we make space available to all students and faculty who request it on lower-capacity, non-production, CGI- and Java-enabled servers.

Using XML on the Server Side

To understand the contribution XML can make to data-driven course Web sites, consider the list of assignments and lecture notes on the course home page in Figure 3. Setting up and maintaining the assignments table with a standard WYSIWYG editor is not too bad, but doing likewise for the lecture notes table with the number and date of each class, the related reading, the lecture topics to be covered, complementary lab activity, and correct URL for each linked element is error-prone even with FrontPage or Dreamweaver. In addition, after you've gone to the trouble to encode the information in `<table>`, `<tr>`, and `<td>` tags, there is nothing else you can do with it. That is, you can't include it on the lecture notes pages themselves and you can't use it to control navigation between related pages as discussed at the beginning of this paper.

Storing the data in XML as shown in Listing 5, however, yields not only the ability to use the data elsewhere, but also the ability to manipulate it easily and use it in a variety of other ways. For example, instead of cutting and pasting table rows as each class moves from "upcoming" to current or passed – a tricky maneuver even in WYSIWYG editors – you simply delete the `status="upcoming"` attribute of the XML file's corresponding `class` element or changes its value to an empty string (`""`). Once the lecture notes and activity for a class are finalized, all you have to do is delete the `suppresslinks="true"` attribute or change its value to `"false"` and the appropriate links will be generated automatically. As before, automatic link generation assures that those links will never be "broken" as long as you follow the appropriate file naming conventions.

```

You can also extract data from the XML file to add to the lecture notes shown in Figure 1. For example, you might want to indicate the topics covered in the lecture and the list of related readings, information which currently only exists in the index on my course Web site. Pulling this data from the XML file would once again guarantee that the two places in which this information appears always agree with each other, eliminating inconsistencies and "out-of-synch" problems. As you might suspect, you can also use the data in this file to address the page navigation issues discussed above.

Thus, the encoding data in XML files and using that to drive the Web site rather than straight HTML provides a wealth of functionality and levels of consistency and integrity much more difficult to achieve in non-data-driven course Web sites. In all fairness, however, I must recognize that some will object to the code-centric view one must adopt to work with XML and will see that as a step backward from today's sophisticated WYSIWYG HTML editors. I concede that this is a legitimate concern today, but some XML editors with well-engineered graphical user interfaces to exist today, and we at UMass Lowell are exploring techniques that will allow the required XML data to be specified via Web forms.

Moving to Student-Centered Course Web Sites

When course Web sites are data-driven and their formatting code is independent of their content, one can begin to explore alternative ways to generate their content, knowing that the display format will remain consistent regardless of who serves as the content author. Using this approach we are beginning to explore a model of course Web site development and maintenance that puts students in the center of the process as *course scribes*. In addition to providing a way to get timely information on-line without burdening professors with yet another responsibility, this approach will hopefully get students more actively involved with the subject matter and its treatment in the course. Such involvement would undoubtedly enrich the individual scribes' learning as well as that of their fellow students following the classic adage: "If you really want to learn something, teach [or explain] it to someone else."

We also expect that when students rather than professors put material on-line, there will be more discussion among peers about the accuracy of the Web site content. It would be ideal if this activity fostered an environment in which students learn from and critique each other's work in the same way that journalism students do when putting together a campus newspaper or literature students do when editing submissions to a literary magazine. Students readily accept that they and their peers make mistakes, while they implicitly – although, of course, erroneously – assume that whatever their professors post is correct. Such discussions are one of the fundamental tenets of cooperative learning, which has been shown to produce significant positive effects on student achievement (Slavin, 1996).

Designing Authentic Activities in Web-based Courses

Jan Herrington
School of Communications and Multimedia
Edith Cowan University
Australia
j.herrington@ecu.edu.au

Abstract: Influenced by constructivist philosophy and advances in technology, there is increasing interest in authentic activities as a basis for learning in both face-to-face and web-based courses. Whereas traditionally, activities have primarily served as vehicles for practice of skills or processes, a more radical approach is to build a whole course of study around authentic activities and tasks. This presentation will put the case that the value of authentic activity is not constrained to learning in real-life locations and practice, but can be analysed for the critical characteristics that help to enhance learning in online contexts. It will continue with a description of the theory, research, and development initiatives that provide the foundations for this approach. Finally, guidelines for the design of complex authentic activities for online learning and examples will be presented, together with the implications of this approach for teachers, students and designers.

Introduction

Teachers have long recognised the advantages of learning in authentic situations. The apprenticeship system was once the primary method for education and training in skills and processes relevant to the workplace. Professional practice, where students spend days or weeks performing in the workplace, is an authentic method for learning the practices of a profession. In higher education and schools, teachers facilitate groups of students performing authentic practices with real consequences and outcomes: students are assisted to form fully operational businesses, to diagnose illnesses in real patients, to form video and multimedia production teams with real clients, and to conduct scientific experiments and data collection on the Internet.

The merits of such engaging and authentic learning environments have been well documented, particularly in reference to situated learning (e.g., Honebein, Duffy, & Fishman, 1993; Brown, Collins, & Duguid, 1989; McLellan, 1996; Duffy, Lowyck, & Jonassen, 1993; Wilson, 1996; McLellan, 1997; Bennett, Harper, & Hedberg, 2001; Luca & Oliver, 2001). Nevertheless, the evidence for real-life experiences is not always positive. For example, in discussing apprenticeships in relation to situated cognition, Wineburg (1989) noted: 'No doubt some apprentices find their apprenticeship absolutely authentic, but I can imagine others who find it absolutely tedious, inefficient, repressive, servile, tradition-bound, and in some cases, downright mean' (p. 9). Lave and Wenger (1991) also noted that the quality and consistency of apprenticeships vary enormously. They argued that apprenticeships do not inevitably result in learning in practice. Included in a series of case studies, they give the example of apprentice butchers who were used in ways more consistent with profit-making than incorporating them into the practice of meat-cutting. For example, a new apprentice might be assigned to the automatic wrapping machine and stay on that single task for years until a new apprentice comes along. Lave and Wenger argued that the apprenticeship itself is not the issue. There can be apprenticeships where 'masters prevent learning by acting in effect as pedagogical authoritarians' (p. 76). The critical issue for them, and the real value of these experiences, is the 'legitimate peripheral participation' the apprenticeship allows. Even when real experience works well, it is not always possible for teachers to organise these authentic learning experiences in real life settings for reasons such as the limitations of the subject matter, practical constraints such as physically moving students to locations of practice, and precautions against risk of danger to students.

The argument advanced in this paper is that the value of authentic activity is not constrained to learning in real-life locations and practice, but can be analysed for the critical characteristics that help to enhance learning. Lave and Wenger (1991) cautioned that the conception of situated learning was substantially 'more encompassing in intent than conventional notions of "learning in situ" or "learning by doing" for which it was used as a rough equivalent' (p. 31). The challenge they put to researchers was to identify the critical aspects of situated learning to enable it to translate into teaching methods that could be applied in the classroom. Together with my colleagues, the purpose of my current research is to distil those elements that contribute to the success of authentic learning environments, to analyse the antecedents and mediating variables, and to provide guidelines for the design of activities to embody those characteristics. Such characteristics can then be applied in a variety of learning contexts, such as simulations, case studies, role-plays, and scenarios, in the classroom and in online learning situations.

Authentic Activities

Activities, investigations and problems have always been at the heart of student involvement in meaningful learning contexts. Teachers provide such activities to enable students to interact with the learning environment, and to learn, apply and practice newly acquired skills. Activities have been defined by Brophy and Alleman (1991) as: 'Anything students are expected to do, beyond getting input through reading or listening, in order to learn, practice, apply, evaluate, or in any other way respond to curricular content' (p. 9).

However, a well-designed activity can be so much more than an opportunity for students to practice and apply their learning. In this paper, it is proposed that the activity students perform as they complete a course of study is the single most important element in the design of the learning environment. A complex and sustained activity can motivate students to learn. It can provide meaning and relevance to complex content, enable collaborative problem solving, justify the creation of polished products, and provide integrated assessment of achievement. It can be the central organising element of an entire course of study.

There is no lack of research and literature written on the use of authentic activities over the past decade or more. There has been a great deal written about the differences between the kinds of activities and problems we face in real-world situations and those typically designed into courses of study. For example, Sternberg, Wagner and Okagaki (1993) differentiated between the kinds of problems learners face in academic situations and practical, real-world applications. They contended that academic problems tend to be: formulated by others, well-defined, complete in the information they provide, characterised by having only one correct answer, characterised by having only one method of obtaining the correct answer, disembedded from ordinary experience, and of little or no intrinsic interest. For example, it is unlikely that the following typical mathematics textbook exercise would ever be encountered in this form in any real context, or that students would necessary know when to apply it in appropriate circumstances:

$2x + 1 = 7$. Solve for x

Similarly word problems, while attempting to provide a real-world context, fail to replicate the essential elements of a meaningful and realistic problem. For example:

> Jenny and her friend left Strasbourg to visit a winery. They bought 3 one-litre bottles of wine, 5 bottles each containing 750 millilitres and two half-litre bottles of wine. What was the total quantity of wine bought?

Why does the student need to know how much wine Jenny bought? If the total was needed to write on a customs declaration, or Jenny needed to calculate her likely blood alcohol level after consuming this wine, this is important contextual information that is missing from the problem description. As it stands, the problem remains a simple and pointless algorithm dressed up with a few words. Bottge and Hasselbring (1993) have pointed out that such word problems are inadequate because: they describe situations in a textual rather than a contextual form; they typically include key words such as 'in all' or 'how many more' that can trigger a specific number operation—unlike real problems that offer no such clues; and there is usually only a single correct answer, which takes only a few minutes to solve (p. 36). Such activities often lead only to an enculturation into the practices of classrooms rather than the real-world transfer teachers expect. Clayden, Desforges, Mills and Rawson (1994) noted that students' efforts to make sense of classroom activities generally lead them to focus on working practices rather than abstract ideas. 'What they learn ... is how to do work, how to be neat, how to finish on time' (p. 164).

In direct contrast to the academic approach, practical problems tend to be characterised by: the key roles of problem recognition and definition, the ill-defined nature of the problem, substantial information seeking, multiple correct solutions, multiple methods of obtaining solutions, the availability of relevant prior experience, and often highly motivating and emotionally involving contingencies (Sternberg et al., 1993, p. 206). Key differences between the school-based approach and real life approach have also been developed and summarised by Lebow and Wager (1994) (Table 1).

Table 1: Real-life versus in-school problem solving (Lebow & Wager, 1994)

Real-life	In-school
1. Involves ill formulated problems and ill structured conditions.	1. Involves 'textbook' examples and well structured conditions.

67

2.	Problems are embedded in a specific and meaningful context.	2.	Problems are largely abstract and decontextualized.
3.	Problems have depth, complexity and duration.	3.	Problems lack depth, complexity, and duration.
4.	Involves cooperative relations and shared consequences.	4.	Involves competitive relations and individual assessment.
5.	Problems are perceived as real and worth solving.	5.	Problems typically seem artificial with low relevance for students.

While the differentiation between the two approaches is largely within the context of school (and to some extent university) classrooms, the same distinctions may be drawn for the design of online learning environments. In completing activities and solving problems, students frequently learn to invoke 'sub-optimal' schemes to enable them to proceed, rather than deal with the content in a way that promotes true understanding. Many of these online programs are so 'well designed', they fail to account for the nature of real-world problem solving, where the solution is rarely neat and the salient facts are rarely the only ones at students' disposal.

In contrast, a number of authors suggest that authentic activities should be ill-defined—students *find* as well as *solve* the problems. Learners need to have the opportunity to: explore a situation with all the complexity and uncertainty of the real world, have a role in determining the task and how it might be broken up into smaller tasks, select relevant information, and find solutions that suit their needs. For instance, Myers (1993) developed three criteria for measuring the authenticity of an activity: (1) the activity provides opportunities for the students to achieve something that they perceive as real or genuine; (2) the activity challenges, inspires and empowers learners to take risks and exceed personal limitations; and (3) the activity makes some difference in the lives of the learners (p. 72). Others have also discussed the importance of providing an authentic context to the task. Jonassen (1991) noted that authentic activities have real-world relevance and utility, and integrate those tasks across the curriculum (p. 29). Similarly, Bransford, Vye, Kinzer and Risko (1990b) described the following criteria of authentic activities that maximise the effectiveness of the approach:

- A single complex problem should be investigated by the students
- Students identify and define their own questions
- Students must have the opportunity to experience the problem from a number of different perspectives
- Students work on the problem over a 'reasonably long period of time' (p. 394), that is weeks rather than days
- Activities are logically related to the problem.

Young (1993) has also listed the attributes of real-life problems which need, where possible, to be replicated in authentic activities. The problem must provide:

- Ill structured complex goals
- Opportunity for the detection of relevant versus irrelevant information
- Active/generative engagement in defining problems as well as solving them
- Involvement of the student's beliefs and values
- An opportunity to engage in collaborative interpersonal activities (p. 45).

Many other theorists and researchers (e.g., Gordon, 1998; Lebow & Wager, 1994) have also emphasised the importance of designing collaborative, rather than independent, learning activities, and others such as Duchastel (1997) have pointed out the importance of diversity, rather than uniformity, of outcome. The Cognition and Technology Group at Vanderbilt (1990b) have stressed the importance of complexity and the necessity to provide an environment capable of sustained examination.

Some argue that it is impossible to design truly 'authentic' learning experiences. Petraglia (1998) argued that authenticity can be neither 'predetermined nor preordained', and such attempts often result in little more than 'preauthentication', that is, 'the attempt to make learning materials and environments correspond to the real world prior to the learner's interaction with them' (p. 53). In supporting this view, Barab, Squire and Dueber (2000) argued that authenticity occurs 'not in the learner, the task, or the environment, but in the dynamic interactions among these various components … authenticity is manifest in the flow itself, and is not an objective feature of any one component in isolation' (p. 38). Petraglia (1998) contended that learners need to be *persuaded* that they are participating in an authentic learning environment. This theme is also adopted by Kantor, Waddington and Osgood (2000) who, when referring to the kinds of goal-based scenarios they designed for Anderson Consulting, argued that: 'It is a simulation of a client engagement in which the participants tacitly agree to go along with an interpretation of job reality which we have crafted' (p. 212).

According to Cronin (1993), the message for designers and teachers of online learning environments is a simple one: in designing authentic activities, 'students' experiences … should more closely resemble the experiences they encounter in real life' (p. 80).

10 Characteristics of Authentic Activities

As described above, many writers and theorists have suggested quite specific design criteria of activities which, if implemented, might enhance students' learning as they engage in tasks that reflect the critical characteristics of genuine roles and activities of professionals in real world settings. In reflecting on the characteristics of authentic activities described by researchers, we have derived ten design characteristics of more authentic activities (c.f., Reeves, Herrington, & Oliver, 2002):

1. *Authentic activities have real-world relevance*
   Activities match as nearly as possible the real-world tasks of professionals in practice rather than decontextualised or classroom-based tasks (e.g., Lebow & Wager, 1994; Cronin, 1993; Oliver & Omari, 1999; Brown et al., 1989; Cognition and Technology Group at Vanderbilt, 1990a; Jonassen, 1991; Resnick, 1987; Winn, 1993)
2. *Authentic activities are ill-defined, requiring students to define the tasks and sub-tasks needed to complete the activity*
   Problems inherent in the activities are ill-defined and open to multiple interpretations rather than easily solved by the application of existing algorithms. Learners must identify their own unique tasks and sub-tasks in order to complete the major task (e.g., Sternberg et al., 1993; Lebow & Wager, 1994; Bransford et al., 1990b; Brown et al., 1989; Cognition and Technology Group at Vanderbilt, 1990a; Winn, 1993)
3. *Authentic activities comprise complex tasks to be investigated by students over a sustained period of time*
   Activities are completed in days, weeks and months rather than minutes or hours, requiring significant investment of time and intellectual resources (e.g., Lebow & Wager, 1994; Bransford et al., 1990b; Cognition and Technology Group at Vanderbilt, 1990b; Bransford et al., 1990b; Cognition and Technology Group at Vanderbilt, 1990b; Jonassen, 1991)
4. *Authentic activities provide the opportunity for students to examine the task from different perspectives, using a variety of resources*
   The task affords learners the opportunity to examine the problem from a variety of theoretical and practical perspectives, rather than a single perspective that learners must imitate to be successful. The use of a variety of resources rather than a limited number of preselected references requires students to detect relevant from irrelevant information (e.g., Sternberg et al., 1993; Bransford et al., 1990b; Young, 1993; Cognition and Technology Group at Vanderbilt, 1990b)
5. *Authentic activities provide the opportunity to collaborate*
   Collaboration is integral to the task, both within the course and the real world, rather than achievable by an individual learner (e.g., Lebow & Wager, 1994; Young, 1993; Gordon, 1998)
6. *Authentic activities provide the opportunity to reflect*
   Activities need to enable learners to make choices and reflect on their learning both individually and socially (e.g., Young, 1993; Myers, 1993; Gordon, 1998)
7. *Authentic activities can be integrated and applied across different subject areas and lead beyond domain-specific outcomes*
   Activities encourage interdisciplinary perspectives and enable diverse roles and expertise rather than a single well-defined field or domain (e.g., Bransford, Sherwood, Hasselbring, Kinzer, & Williams, 1990a; Bransford et al., 1990b; Jonassen, 1991)
8. *Authentic activities are seamlessly integrated with assessment*
   Assessment of activities is seamlessly integrated with the major task in a manner that reflects real world assessment, rather than separate artificial assessment removed from the nature of the task (e.g., Reeves & Okey, 1996; Young, 1995; Herrington & Herrington, 1998)
9. *Authentic activities create polished products valuable in their own right rather than as preparation for something else*
   Activities culminate in the creation of a whole product rather than an exercise or sub-step in preparation for something else (e.g., Barab et al., 2000; Gordon, 1998; Duchastel, 1997)
10. *Authentic activities allow competing solutions and diversity of outcome*
    Activities allow a range and diversity of outcomes open to multiple solutions of an original nature, rather than a single correct response obtained by the application of rules and procedures (e.g., Duchastel, 1997; Bottge & Hasselbring, 1993; Young & McNeese, 1993; Bransford et al., 1990a; Bransford et al., 1990b).

Investigating Authentic Activities Online

As stated by Lebow and Wager (1994): 'When authentic activity is the model for appropriate learning activity, the perceptions of the learner and the affordances of the environment represent an integral and inseparable context of learner/environment' (p. 241). The Cognition and Technology Group at Vanderbilt (1990b) describe authentic activities as 'generative' because the completion of the task requires the students to generate other problems to be solved. They draw a distinction between these authentic tasks and simple word problems which already define the problem, such as: 'If you travel 150 kilometres at 90 kph, how long will the journey take?' Compare this simple problem with one described by Reeves and Laffey (1999) in an undergraduate engineering course where the students' task is to plan a mission to Mars, and to design a research station including a renewable power source to sustain life once a station is established.

Such activities guide learning in entire courses of study. They are not provided simply to enable students to practice skills taught in more didactic, content-focussed ways. They are integral to the way students approach and study the course, and provide meaning to complex curricula.

At Edith Cowan University, a *Graduate Certificate in Online Teaching and Learning* has been developed according to the guidelines of authentic activity described above. The aim of the course is to assist teachers to have the confidence to design and plan effective online learning environments. The course consists of four units: *Online Teaching and Learning, Resources for Teaching and Learning Online, Designing Effective Online Learning Environments,* and an *Online Learning Project Unit*. The design of the units is characterised by strongly student-centred environments, with authentic and contextualised learning tasks in collaborative settings, using integrated assessment strategies and learning scaffolded by teacher support. The units are designed to be delivered online and to embody a variety of online teaching and learning strategies.

The first unit entitled *Online Teaching and Learning* (Figure 1a) was designed to explore issues associated with the creation of effective learning environments, and draws heavily on recent theory and research. The unit is based upon a task (Figure 1b) where the student takes on a role in a scenario set in a fictitious university. The student is required to evaluate a website that has been set up as an exemplar for a consortium of universities planning to develop a joint online course. The students then, in collaboration with other students ('representatives from the other universities') recommend a set of guidelines for website development, and then redesign the original website (or one of their own choosing) according to those guidelines. While comprising a single sustained task, the activity can be evaluated at three points.

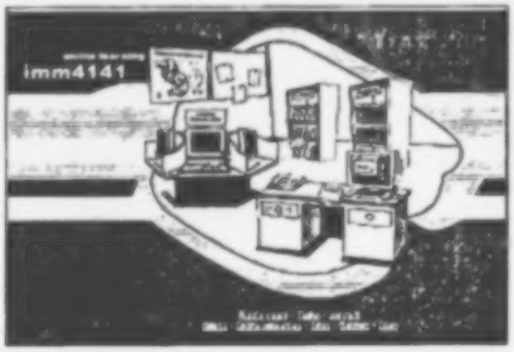

Figure 1a: The main interface for *Online Teaching and Learning*

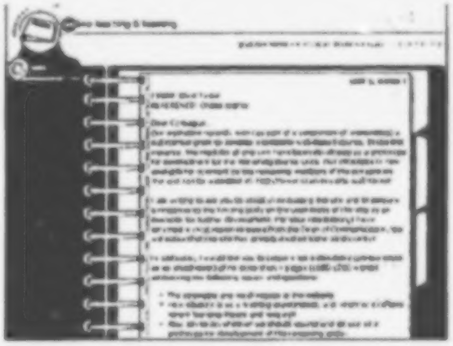

Figure 1b: The task is presented as a memo

Our current research funded by the Australian Research Council, entitled *Authentic activity as a model for web-based learning* has sought to investigate examples of courses or units that embody the critical elements described above. Using these characteristics as criteria for the selection of appropriate courses to study, our research has sought to investigate the characteristics of authentic activity that facilitate a whole course unit of study being encapsulated within complex tasks, and to determine the factors that contribute to the successful adoption and implementation of activity-based online course units. We have used the criteria listed above to select courses or units of study that use authentic activities as a central core of their presentation. The units must have a major online component, not simply comprise supplementary material to on-campus delivery. Examples of the types of online courses that use authentic activities are given below.

In a post-graduate unit entitled *Research Preparation: Research Methods*, students do not learn research methods by studying texts describing research methodologies and appropriate applications. Instead they work virtually in a graduate research center (Figure 2a) where they are given the task of investigating the closure of a rural school. They do this using both qualitative and quantitative methods, and they are assisted by two virtual researchers who have collected data from the community and assembled it in a raw form in the center. The students can examine school records, population data, interviews with teachers, parents and community members, newspaper reports and other documents (e.g., Figure 2b). Students produce a report that analyses the impact of the closure of the school on the rural community.

In a semester course entitled *North American Fiction and Film*, (Figure 3a) students study novels written by North American writers such as Melville, Hemingway, DeLillo, Vonnegut, Atwood, and Esquival, and they view film versions of the same works (if appropriate). In the course, they are given the role of Editorial Board Members of an online scholarly journal (Figure 3b), to which they submit book reviews and articles based on their study of the literature. The students collaboratively design a guide for novice reviewers on how to write a book review. The teacher of the course is the journal editor, and an edition of the journal is published online at the end of the semester. A range of literary resources, articles and reviews are accessible from the website. The theoretical and design framework of the course is described in Fitzsimmons (2001).

Coastal and Marine Systems is a post-graduate unit where activities are specifically designed to mirror the typical problems that a coastal manager or an environmental consultant might encounter. For example, in one major task (Figure 4a), it is proposed that a marina has been developed, and as part of the approval, annual monitoring of water quality is required. The monitoring encompasses water inside the marina as well as a site several hundred meters outside the marina, in well-flushed ocean conditions. The students are provided with a set of real data collected by the course teachers from inside and outside the marina, and they are required to understand, analyse and interpret the data and draw conclusions as to whether the water quality within the marina is different to that outside, and if so explain the possible causes. The evaluation is presented as a report within the context of the renewal of the marina license. The course is constrained, to a degree, to the requirements of the proprietary software, Blackboard (originally the plan included a more realistic interface with clickable visual links and metaphors) (Figure 4b) but nevertheless, the task incorporates the characteristics of authentic activities described earlier.

In another example of complex activity, Pennell, Durham, Orzog and Spark (1997) described a web-based environment, *Writing in Organisations*, part of the third-year curriculum for Bachelor of Arts (Communication Studies) where students learn business communication skills by accepting temporary employment in a virtual recording company (Figure 5a). They are given a complex task to complete, where they need to prepare a report on whether the company would benefit from the introduction of an internal newsletter. In order to complete this activity, they make appointments, keep a diary, 'interview' the director and other employees (Figure 5b), and write letters, and memos as required.

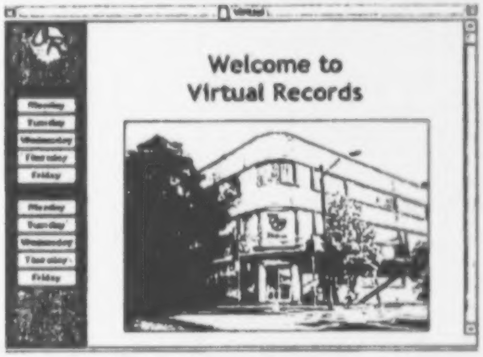

Figure 5a: Main interface of Virtual Records

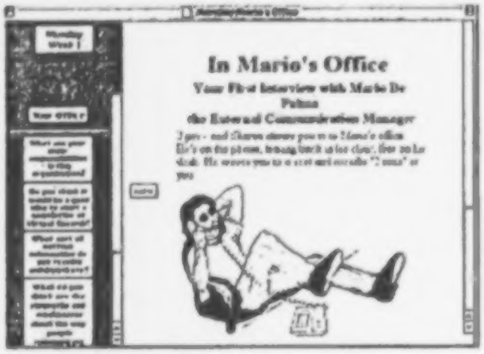

Figure 5b: Interviewing one of the employees

While most of the learning environments studied have involved the creation of simulated work places and often incorporate extensive resources such as graphics, video, and sound files, other examples studied are less resource intensive while still retaining fidelity to the authentic characteristics described. For example, in an introductory biology course for online delivery (described in Koenders, 2002) students investigate a simulation of the discovery of new life forms, and are introduced to the interpretation of microscopic images of cellular structures. In the scenario, students are given a role as biologist—one member of an expedition to a remote lake in Siberia where several microorganisms are found that cannot be classified. They 'collect' the specimens and return to the university to analyse them. On the website, they are provided with images of unicellular organisms apparently unknown to science. Students are assigned to groups of four where they analyse the specimens and prepare a report. The scenario is not drawn in an elaborate, resource intensive manner, but built up through the creation of an interesting and engaging idea.

The learning environments described have varying degrees of fidelity to the characteristics of authentic activities defined earlier, but all have strong linkage to real-world professional practice. Teachers, authors, instructional designers, tutors and other associated with the design and delivery of the courses are being interviewed, and the websites analysed. Student responses are being gained through online questionnaires. The research is ongoing, and analysis is focusing on the identification of conceptual

BEST COPY AVAILABLE

themes and issues emerging from the data, using techniques such as clustering, and making contrasts and comparisons (Miles & Huberman, 1994).

Some Issues Arising from the Research

While analysis is preliminary at this stage, several trends have emerged, and there are implications not only for the design of online learning environment, but also for the teaching and learning of such courses, and further research efforts .

Generally, the teachers involved in units and courses featuring complex, authentic activities (as described above) are enthusiastic and positive about their teaching and about the quality of student learning in the course. All have found the experience of designing and teaching the course to be professionally enhancing, through their own learning of recent educational research and pedagogy, through the experience of teaching in new and innovative ways, and in many cases through publications and conference presentations about the course and other professional activities.

One theme which has emerged strongly from a number of different sources in our research is the nature of authenticity, and how 'authentic' environments are often the creation of the teachers', authors' and instructional designers' imaginations, and are thus inevitably someone's *view* of what is authentic. Petraglia (1998) has been critical of this shortcoming, calling it 'the real world on a short leash' (p. 53). There is nevertheless, much evidence to suggest that these learning environments can provide a great deal of meaning to otherwise decontextualised facts and skills, and can enhance the transfer of deep and lifelong learning (Barab & Landa, 1997). At what point do students become engaged, if ever, in these scenarios? Is there a pattern to their acceptance of the terms of the authenticity, and how important is the suspension of disbelief? (Herrington, Oliver, & Reeves, 2002).

Another recurring theme is time, in terms of both the teachers' and the students' commitment to authentic activities. Many of the teachers interviewed to date have mentioned the inordinate amount of time involved in both the preparation of the authentic tasks and environments, and the teaching of the online course. Teachers also reported that students were likely to spend much more time on the tasks, some complaining of the demands, others appreciative of the sense of deep engagement they experienced with the learning context. The time commitment problem has also been noted in many other authentic learning environments, some of which have reverted to more traditional modes despite strong evidence of effectiveness, including the Mission to Mars engineering course described earlier (Reeves & Laffey, 1999). If the large time commitment is a 'labor of love', willingly given by the intellectual owners of the course, it is also likely that this commitment is not sustainable over the long term, and courses based on authentic tasks will be abandoned for more manageable—and more traditional—lecture/tutorial modes of instruction.

Proponents of authentic activities as described here are generally enthusiastic and committed teachers who willingly provide time and effort beyond the usual expectations. Further research may help to identify authentic activities in online units that are offered to large student cohorts. Investigation of large scale, successful initiatives will possibly yield a great deal of information on how these environments can be sustained with standard resources and faculty allocations, rather than an abundance of goodwill and generosity on the part of teachers. Longer term studies may also reveal the kinds of support that host institutions can develop to facilitate course units employing authentic and complex activities.

It is hoped that analysis of our own and further research data will help to suggest those characteristics of authentic activity that facilitate a whole course unit of study being encapsulated successfully within complex tasks, and to determine the factors that contribute to the successful and sustainable adoption and implementation of activity-based online course units.

E-LEARNING IN HEALTH CARE
EMERGING TRENDS
(Policy, Practice, Evaluation, and Technical Implications)

Dr.Penny Jennett
Professor, Faculty of Medicine
Head, Health Telematics Program
University of Calgary
Canada
jennett@ucalgary.ca
(adapted from other presentations, sources and papers)

Introduction

Important ingredients to selecting appropriate e-learning tools for this electronic age are: 1) a clear understanding of the changing nature of practice and professional learning and 2) an awareness of recent e-learning frameworks to assist in making choices. This presentation will review current directions in professional workplace learning, address related implications for e-learning, outline guidelines that can be used when making choices specific to e-learning tools, and suggest new ways for assessing the impact of using such tools. The discussion will close with reference to change and accountability. Two concrete examples of e-learning projects will be referenced.

Body

Wenger (1998) in his reference to communities of practice (Tab. 1) invites us to consider learning within the health renewal process. Professionals in the workplace are faced with new ways of learning and practice. A re-definition of knowledge is core to this change. Knowledge, driven by workplace learning, now includes tacit knowledge, explicit (evidence-based, empirical) knowledge, knowledge of relationships, and knowledge created from collaboration. Quality of care and learning are tied together through team performance and health outcomes (Frankford, et al., 2000, Cervero, 2000). As a consequence, workplace learning environments invite cooperative interdisciplinary learning at points of care. They also facilitate "capability" - the ability to adapt to change, generate new knowledge, and continuously improve performance (Fraser & Greenhalge, 2001).

Progressive pedagogies, (including e-learning), erase barriers within the continuum, encourage lifelong learning through practice reflection, as well as the sharing of knowledge across organizational and hierarchical boundaries. The development of communities of learning, within and between organizations, is fostered (Wenger, 1998). Given this context, a number of guidelines can be used when selecting e-learning tools.

First, it is helpful to appreciate the ways that e-learning tools can be categorized. Definitions and examples of categories are outlined in Table 2. Before choosing or purchasing specific tools, health professionals can reflect on which type(s) of tools are required to achieve and optimize the task at hand

When choosing electronic aids, it is also important to consider both the characteristics and the capabilities of the chosen tools (Tables 3 & 4). Table 3 outlines 13 characteristics to be considered before purchase and implementation. Table 4 outlines a number of functions that may be required to support and achieve a learning task. Optimal learning will be achieved when users review such guidelines, and decide which characteristic/function, or combination of characteristics/functions, is optimal. By being aware of the characteristics and capabilities of an e-tool, the user can recognize the strengths and limitations of it, and consequently better apply and use it within the workplace.

Further, new frameworks are now evolving specific to research and evaluation. For example, Action Research, (Stringer, 1996), Design Experiment Methodologies, (Brown, 1992), Collins, Brown, & Newman, 1989), Return on Investment models, (Stacey, 2002), and Information literacy research approaches (Cheuk, 2000) are being applied.

Change and areas of accountability are shifting, given these evolving concepts, definitions, and assessment approaches. This change impacts workplace learning settings, health organizations, as well as the health and learning systems. The culture of learning is now such that stakeholders become communities that learn collectively, health professionalism becomes a continuum of education and practice, and learning with technology transects traditional organizational boundaries. Technology is not only a medium, but also a catalyst for human development and change (cultural, organizational, system, and economic). For example, standards, accreditation, certification, and licensing issues arise, as do confidentiality/privacy/security, partnership, and intellectual challenges.

Conclusion

As the nature of practice and workplace learning evolves, so must the expectations of e-learning tools within this context. Decision-making frameworks are helpful as the electronic age emerges. Changes and areas of accountability within the workplace culture, the communities of learners, the organization, and the system are issues to be articulated and understood. The paper has been written to facilitate this process.

TABLE 1: E-Learning within the Health Renewal Process

> *"...once education is understood in terms of identity, it may no longer seem such a good idea to front-load 'education' ... Identity formation is a lifelong process whose phases and rhythms change as the world changes. From this perspective, we need to think about education not merely in terms of an initial period of socialization into a culture, but more fundamentally in terms of rhythms by which communities and individuals continually renew themselves."* (Wenger, 1998)

TABLE 2: Classifications for Technologies

Practice Support Systems
Technology applications that can assist practitioners to integrate knowledge and learning into practice (point of care)
Examples:

- Expert Systems, Decision Support systems
- Error-detection or flagging mechanisms
- Personal Digital Assistants (example – clinical practice guidelines)

Health Information Systems
Searchable databases of medical information that practitioners can use at the point of care
Examples:

- Electronic health records
- Electronic prescription systems
- Network-based databases – e.g. exchange of radiology images and laboratory data
- Online knowledge services

Communication Facilitation Technologies
Technologies that support and enhance communication between team members
Examples:

- E-mail and listservs
- Chat groups
- IP based videoconferencing and date sharing
- Visualization technologies (digitalization, virtual whiteboards, etc.)
- Virtual reality environments

Collaborative Learning & Knowledge Building Environments
Technology that facilitates the advancement of knowledge and improvement in practice
Examples:

- Learning environments that deliver a best practice module in pain management
- On-line collective learning sessions

Adapted from the Office of Learning Technologies (OLT) report (2001)

TABLE 3: Characteristics of e-Health Tools

- Simplicity
- User Friendly
- Interoperable
- Affordable
- Sustainable
- Open Standards
- Portable
- Scalable
- Robust and Reliable
- Networked
- In keeping with Privacy, Confidentiality, and Security guidelines
- Computable with diverse transmission modes (i.e. wireless, wired, satellite

TABLE 4: Functionalities for E-Health Tools

Tools which will:

- Serve the learning continuum- undergraduate, graduate clinical, graduate science, continuing professional development
- Enable multi-disciplinary, inter-professional collective team performance
- Enhance health and health care outcome (tying quality of care, patient safety, and learning together)
- Facilitate learning in practice
- Support learning across organizational/hierarchical jurisdictional boundaries.
- Serve as a medium, but also a catalyst, for Continuing Professional Development and change
- Support continuous improvement
- Provide point of care, jut in time learning; as well as reflective intended learning

Abstract: As more and more institutions and companies in Canada develop online learning content, the importance of learning objects and the metadata used to describe them becomes clear. EduSource has brought together Canada's leading experts, researchers and practitioners in the field of E-Learning for the purpose of defining and testing a world-class infrastructure for learning object repositories (LOR) and to produce a Repository in a Box prototype that will include metadata guidelines, software tools, hardware specifications, best practices and methods for generating communities of use that would allow any organization to build and connect their own repositories.

Summary

The eduSource project is a pan-Canadian collaborative project to create a testbed of linked and interoperable learning object repositories. The project is providing leadership in the ongoing development of the associated tools, systems, protocols and practices that will support such an infrastructure. The primary delivery mechanism for this testbed will be the broadband Internet, and in particular CA*Net 3/4. This project is based on national and international standards; it is fully bilingual; it will be accessible to all Canadian including those with disabilities; and it will share and disseminate its findings across Canada and internationally. Each of the partners and their associates are bringing considerable resources to the project. Collectively the contributions of the partners amount to $5,280,000 of the total project value of $9,830,000, CANARIE is contributing up to $4,500,000.

To simplify its activities, eduSource has six designated primary partners who will lead this work – Athabasca University, the Netera Alliance, (New Brunswick Distance Education Network (NBDEN), the New Media Innovation Centre, Téléuniversité du Québec, and the University of Waterloo – with the Netera Alliance serving as the lead contractor. In addition it will include a host of associates in the private and public sector representing learning institutions from across the country.

EduSource takes advantage of, and enhances, the capabilities of each of its members in building a comprehensive LOR implementation infrastructure. NBDEN will work with the NewMIC Foundation to explore the development of Repository Content. NBDEN will also work with TeleEducation NB, the National Research Council, and private sector partners such as RightsMarket Inc. to investigate Digital Rights Management for LOR's. Télé-université with le Centre de recherche LICEF and the Advanced Technologies for Learning Unit of the University of Alberta will provide a testing and evaluation framework for the project. Athabasca University will lead in the ongoing development of the CanCore metadata application profile. Télé-université will coordinate the integration and development of software packages such as Explor@ - II, CAREO (Campus Alberta Repository of Educational Objects), ALOHA (from the Learning Commons at the University of Calgary) and SPLASH (from the POOL project) and lead the development of new software packages. Netera and NewMIC will continue their work in hardware and network integration. The University of Waterloo will contribute its knowledge of and international collaborations in community building, as well as its expertise developed in the CANARIE Learning

Program's PLIANT (**Partnerships for Learning, Innovation and Technology**) project. Netera will provide project management, coordination and communications for the project as well as examining new Business and Management Models.

Project Objectives

The primary objective of the project will be the design and testing of a prototypical but functional, national learning object repository infrastructure and the development of specifications and tools for a "Repository in a Box" that can be shared with organizations across the country. This will be accomplished by bringing together Canada's leading experts, researchers and practitioners in the field to share best practices for the large-scale, country-wide deployment of a network of learning object repositories.

In this context, the project team has identified four broad goals for the project:

1. Tto promote and refine a repository metadata framework through the ongoing development of the CanCore protocol;

2. To support experimental research in key areas such as pedagogy, accessibility, protocols, network engineering, hardware integration, quality of service, security, rights management, content development and software applications;

3. To implement a national testbed to investigate processes such as peer review, content repurposing, user support, professional development and content transactions; and

4. To communicate and disseminate its findings through cooperation and partnership with other federal and provincial agencies, institutions and the private sector.

To meet these goals, the eduSource project has identified a number of specific objectives:

1. *It will address and examine issues of interoperability by connecting a critical , mass of learning objects housed in repositories across the country.*
   Specifically, it will first link together existing collections of learning objects such as BELLE's Alexandria Repository and the Math Resources website at Simon Fraser University and secondly it will provide the tools for other communities, such as SavoirNet and CIRTA (Centre interuniversitaire de recherche sur le téléapprentissage) in Quebec to create and connect their own content and repositories to this pan-Canadian network. In this manner a sufficient number of learning objects of various types can be created, adapted, packaged and tested.

2. *It will play a leadership role in developing and promoting national and international standards.*

   Already eduSource members participate in a variety of IMS, IEEE and other international working groups. Members are part of an international network working to develop and implement the Educational Modeling Language. This new project will provide a framework for these experts to continue to contribute to the ongoing development of internationally recognized metadata specifications.

3. *It will develop a blueprint for the rights management of learning objects.*
   The objective here is to design a rights management structure, built on internationally recognized standards, for use by the repositories participating in this national initiative and to integrate this work with the project's software tools.

4. *It will link and integrate the development of repository software programs.*
   In the first phase of the CANARIE E-Learning Program eduSource partners and associates produced a host of valuable software tools for building repositories. These include Explor@ - II for managing resources and repositories and integrating learning objects within courses and learning events; CAREO for searching and building centralized repositories; ALOHA for metatagging objects in CanCore; and SPLASH for creating peer-to-peer repository networks. The

objective of this phase of the work is to integrate and extend those packages to provide a comprehensive suite of tools to build, link and use repositories.

5. *It will create a physical testbed of servers linked together through CA*net 4.*
   As in Software Development, the focus of this objective will be in integrating existing testbeds. The BELLE, POOL, CanLOM, APCCC (Atlantic Provinces Community College Consortium) and SavoirNet projects are some of the existing or proposed repositories that will be molded into a single, shared network for the creation, management and distribution of learning objects using both client-server and peer-to-peer applications..

6. *It will build a bilingual pan-Canadian community of practice.*
   Under the leadership of Tom Carey at the University of Waterloo, the BELLE, PLIANT, POOL and SavoirNet communities of use are being linked together to form a critical mass of instructors, teachers, technology coordinators, instructional designers and content producers. All partners have made a commitment to provide materials in both official languages. Canada can and should play a pivotal role in ensuring that multilingual capabilities are an inherent part of LOR development.

7. *It will examine new business and management models for object repositories.*
   EduSource is developing models for the ongoing sustainability and commercialization of its testbed. In particular, the leadership role that Canada is playing in this area will be investigated for its potential to generate international export opportunities.

8. *It will develop a communications plan for the dissemination of these results.*
   A comprehensive plan will be designed to speed the flow of information between eduSource partners and associates as well as raising awareness throughout the country about the importance and value of this work.

9. *It will accomplish these goals within the context of a comprehensive program of evaluation and feedback.*
   Evaluating the effectiveness of learning objects in educational environments is critical to the success of this repository project. Based on the experiences of the LICEF's LORIT Laboratory at Télé-université and the Advanced Technologies for Learning Unit of the University of Alberta, the project will ensure consultation and input from a broad spectrum of educators and learners from across Canada.

10. *It will make certain that that these repositories will be accessible to all Canadians and particularly to those learners with disabilities.*
    Through an alliance with Jutta the Adaptive Technology Resource Centre, at the University of Toronto (ATRC), eduSource will be linked to and compliant with the Centre's guidelines for accessibility. EduSource will work with them through their Barrierfree On-line Learning Exchange or BOLE project in order to make our network of repositories accessible.

Project Description

Canada's recently announced Innovation Strategy is predicated on an ever-increasing supply of well-educated and skilled workers in all parts of the economy and in all parts of the country. Learning object repositories are the first step in ensuring that this demand can be met. Individual provinces. learning institutions and even the private sector are all capable of developing their own separate and discrete repositories but the value of these projects grows exponentially when they are connected together.

EduSource will be designed around a series of complementary and interwoven work packages. What holds these pieces together is the idea of developing and testing a shared prototypical "Repository in a Box." Each package has been designed to support this concept and taken together they provide much more than just a testbed for a network of linked repositories – in effect, they provide the blueprint for others all across Canada to create a proliferation of repositories that can all work and communicate together. Each of these packages is described in detail below.

Repository Content Development

Package Managers: NBDEN and NewMIC Foundation
Key Participating Partners: University of Waterloo; Télé-université

The key to this package is to develop a critical mass of content to test the capabilities of the proposed network. This will be accomplished by a multi-part strategy. The package managers will develop and provide the interfaces, templates and protocols necessary to connect existing and developing learning object repositories across Canada and internationally and ensure interoperability.

Secondly, content from all the project partners and associates will be repurposed. In association with the Community Building partners, learning objects will be authored by diverse communities and institutions from across Canada.

Thirdly, using the content developed in stages one and two, learning objects of various types will be created, adapted, and tested. This includes the storage, indexing and segmentation of media types ranging from text to Java Applets; the development of archival standards for digital masters; and an evaluation of the effectiveness of the delivery of these objects through a variety of means including broadband, medium band and satellite networks.

NBDEN and its partners will use the CanCore specification to build the next generation of CanLOM – the pan-Canadian Learning Object Metadata directory, which will be based on the TeleCampus. CanLOM is not a learning object repository, but rather a database containing the metadata necessary for the exchange and interoperability of learning objects housed in repositories across Canada and in other countries. Partners are working together to present a comprehensive strategy for the widespread adoption and implementation of the CanCore metadata profile through CanLOM and through repository projects across Canada.

Digital Rights Management
Package Managers: NBDEN with NRC

Based on the explorations and research of the National Research Council, a digital rights management (DRM) approach will be developed for the project. This package will begin with a comprehensive survey of the literature in the fields of commerce and information management on the current state of DRM theory and technology and will look at emerging international standards such as the Open Digital Rights Language (ODRL).

Based on this research a series of recommendations regarding DRM will be prepared and presented. These will include an XML (Extensible Markup Language) DRM schema which can be used as a standard complement to the CanCore profile. These components will be used to design a rights management structure for repositories participating in this national initiative. Mechanisms for using this specification will be integrated into the project's suite of software tools.

Testing and Evaluation
Package Managers: Netera and Télé-université

Partners will implement a project evaluation strategy designed to maximize learning, knowledge accumulation and dissemination and knowledge transfer. This work will be accomplished through well-established stages such as Outcome Definitions, Needs Assessment, Formative Evaluation, Summative Evaluation and Learning from the Collaborative Process. A summative evaluation will assess the impact of the project on practice within the participating organizations. It will also assess the project's success at meeting the initial project goals. Data will be gathered through extensive interviews with key partners, associates, funders, surveys of end users and functional review of products produced during the project.

Despite the popularity and potential of collaborative funding models with government agencies, there has been little systematic study of their efficacy and little awareness of potential problems and solutions that will better ensure successful innovation. EduSource will develop both theoretical and practical models to inform future projects. Using constant comparative analysis of interview transcript data, minutes of meetings, project documentation and investigator observation, the researchers will build theory that identifies the most effective type of collaborative organization, barriers and motivators for collaboration and types of organizational structure most conducive to effective collaboration both within the partnering organizations and of the collaborative organization.

Metadata Development

Package Managers: Athabasca University and NBDEN
Key Participating Partners: Télé-université

Metadata is what separates repositories from the chaos of the World Wide Web. In this respect, the development of the CanCore metadata profile is one of the most important deliverables of the entire E-Learning Program. EduSource will build on this success and further Canada's leadership in this area. The partners are developing, extending and reinforcing the CanCore, including the development of a French language version.

Partners will work on extensions to the specifications to integrate distance learning ontologies derived. The actual LOM relational database implementation within the Explor@-II system will complement and directly aid in the implementation of the CanLOM learning objects metadata directory.

EduSource is not merely conforming to internationally recognized metadata specifications, but its members are actively engaged in setting those standards. This project acts as a springboard for Canada to play a prominent role in this area.

Software Development

Package Manager: Télé-université
Key Participating Partners: Athabasca University; NBDEN; NewMIC Foundation; Learning Commons, University of Calgary (in association with Netera)

The partners are developing an integrated suite of software tools for the implementation and management of learning object repositories. These software tools will form the foundation of the pan-Canadian repository network and their development will be coordinated across various institutions. Wherever possible the project will use open source solutions to ensure the adoption and use of these tools across a full spectrum of Canadian and international educational organizations.

A crucial dimension of this work will be the integration of existing software tools developed during the first phases of the E-Learning Program. These include the POOL project's SPLASH for the creation of peer-to-peer networks of repositories; Explor@ II for the management of repositories and resource integration into courses; CAREO for the searching and creation of centralized repositories; and ALOHA from the Learning Commons at the University of Calgary for the metatagging of learning objects. By making these tools work together and augmenting them with some strategic software 'bridges', eduSource will provide a complete set of repository building tools.

But eduSource will also move into new areas of research and development and in particular it will try to harness the emerging capacity of the Semantic Web and Web Services to facilitate teaching and learning. CANARIE projects to date have focused on the formal description, tagging and distribution of educational objects. While this is an important first step, it is well known that successful learning experiences are dependent upon many other factors besides availability of content. Recognizing this limitation a number of researchers have developed educational modeling languages (EML) that formally describe other critical components of the educational transaction. Most importantly EML from the Dutch Open University is expressed in formalized notation (using XML) to facilitate search, retrieval and automatic application of this knowledge on the semantic web by both humans and autonomous agents. The ADISA implementation of the MISA instructional methodology, built by Télé-université's Cogigraph also provides an educational modeling language as a set of XML descriptions that will be compared with EML and possibly combined through an international collaboration with the Dutch Open University

In this context, the software team will develop tools for Repository Interoperability and Development, Knowledge and Information Management, and Facilitating Teaching and Learning.

Hardware Integration

Package Managers: Netera and NewMIC Foundation

Partners will work together to develop a hardware specification for learning object repositories and to create a physical testbed for a large-scale, cross-country implementation trial of learning object repositories using Ca*net 3/4. This work will build on, enhance and integrate existing servers established through CANARIE projects.

The national testbed will be designed to accommodate servers from various vendors and of various sizes, capacities and operating systems as well as exploring different architectures including both peer-to-peer and centralized server models. In all cases this package will be informed by the principles of open systems and interoperability.

The primary delivery mechanism for this network will be the broadband Internet and in particular CA*net3/4 but it will also investigate the delivery of learning objects by other means as well. This will include the commercial Internet and wireless and satellite systems and the use of caching servers and other devices to enhance delivery and performance.

Business and Management Models

Package Manager: Netera

Key Participating Partners: NBDEN; Télé-université; University of Waterloo

During the course of this project, a business and management strategy will be advanced. To this end a variety of funding models will be developed and assessed. These would include memberships, subscriptions, support and service contracts, licences and pay-per-use. This work will be closely coupled with the Digital Rights Management Package.

This work-package will also explore the sustainability of LOR infrastructures between and within educational institutions. Investigations will be made into how learning organizations independently and separately coordinate resources (labour, equipment) to support the creation of educational objects, what challenges exist, and how to redesign organizational processes to engender the long-term sustainability of LORs in education.

The long-term viability of these networks depends on communicating their value and importance to educational institutions, government agencies and the general public. Learning organizations need to understand that repositories are the foundation of online learning and that lessons, modules and courses cannot be delivered through the Internet without a robust repository architecture. The success of eduSource's business model depends on both its testbed and the effectiveness of its communications plan in disseminating its results.

Community Building

Package Manager: University of Waterloo
Key Participating Partner: Netera

The partners will develop networks of exemplary Canadian communities for the design, development, evaluation and exchange of learning objects and these will be informed by the communities of use established by other collaborative projects. In the post-secondary domain, these networks of communities will demonstrate the scalability of online subject area communities to achieve the following objectives:

- Foster collaborations across Canada among community members
- Extend the quality and quantity of learning objects that are developed and re-used
- Enhance understanding and expertise about the design, implementation and use of learning objects
- Establish a distinctive Canadian area of expertise in the international learning object realm.

- Faculty members at universities and colleges are critical to the development of robust networks of communities. Project partners will develop exemplary proto-type networks of discipline-specific online communities to integrate local collaborations within their larger communities of use and link them to eduSource's pan-Canadian network of repositories.

Project Management, Co-ordination and Communications

Package Manager: Netera
Key Participating Partners: All

In consultation with all its partners, the Netera Alliance Inc. is providing project management, accounting and administration for the project as well as fulfilling the reporting requirements as stipulated by CANARIE. cannot be over-emphasized that the success of large-scale projects with multiple partners spread across the country depends on a strong management team.

Project Team

The eduSource team is built on the foundation of the CRAG (Canadian Repository Action Group) which was formed in the summer of 2001 to provide a forum for ongoing collaboration between Learning Object Repository projects.
The members presently include the following:

- Athabasca University (Alberta)
    - Campus Alberta Repository of Educational Objects
    - Distance Education Projects and Technological Help

- New Brunswick Distance Education Network Inc. (NBDEN)
    - TeleEducation NB
    - Atlantic Provinces Community College Consortium
    - Université de Moncton
    - E-com inc.

  - The National Research Council of Canada (NRC)

- Netera Alliance (Alberta)
  - Learning Commons (University of Calgary)
  - Advanced Technologies for Learning (University of Alberta)
  - Callisto
  - Telesat
  - RightsMarket
  - Antarcti.ca.

- New Mic Foundation (New Media Innovation Centre) (BC)
  - Simon Fraser University (Surrey)
  - TelesTraining Inc.
  - C2T2 (Centre for Curriculum Transfer and Technology)
  - BC Institute of Technology

- Téléuniversité du Québec
  - CIRTA
  - LICEF
  - Technologies Cogigraph Inc (TCI)
  - Canal Savoir
  - ETI (Ecole de technologie de l'information)
  - Bell-Technomedia
  - Ecole Polytechnique,

- University of Waterloo

Summary

EduSource is a comprehensive project that ties together various work packages and creates synergies between its partners and associates. All of the partners are Canadian organizations and meaningful work will be carried out in every region of the country. Moreover each partner brings unique skills to the project and the work packages have been organized to ensure that those skills bolster and complement one another. For example, CanCore guidelines are developed in Alberta through Athabasca University but implemented in the CanLOM metadata repository in New Brunswick and in Explor@ in Quebec. In fact, the wide-scale adoption of CanCore demonstrates how the principles of interoperability and open systems have guided our previous projects and are the foundation of our present work together.

Because the project builds on and integrates pre-existing repository work by experienced project teams, eduSource can ensure the soundness of its methods and the feasibility of the technologies involved. In addition not only are eduSource members aware of the best national and international standards, such as CanCore, they are helping to create those standards. All of the partners are connected to CA*net 3 and have helped develop the applications such as videoserving and videoconferencing that exploit its unique strengths. The project addresses issues of accessibility through its partnership with the Adaptive Technology Resource Centre and its Barrierfree On-line Learning Exchange or BOLE project.

The expertise of the team and the members' experience in collaborative product development are powerful indicators that eduSource will be beneficial to the future of the Canadian economy not only through the exporting and commercialization of its results, products and expertise to a growing global market, but also through the significant competitive advantage it will impart to Canada and Canadians through the effective exploitation of broadband networks for the delivery of education and training.

Challenges in Providing e-Learning Solutions in the Regulated Pharmaceutical Industry

James L. Vesper, Learnwright, Inc., Rockville, MD, USA jvesper@learnwright.com

Abstract: Regulatory agencies around the world require that those involved in producing pharmaceutical products be adequately trained. E-learning can accomplish this, providing consistent delivery and learner assessment. However, there are some unique expectations that regulators and the pharmaceutical industry have of e-learning solutions. These include approved electronic records and signatures that have reliability and integrity, system and application validation, and assessment of learning. While these expectations are a challenge to e-learning courseware producers, they contribute to the production of high-quality, robust courseware.

The pharmaceutical industry includes those firms that manufacture prescription and over-the-counter drug products, active pharmaceutical intermediates, biotech pharmaceuticals, and those products derived from human blood and plasma. Manufacturers in this sector must provide knowledge and skill training to personnel who develop, manufacture, and test pharmaceutical products making this sector a prime candidate for using web-based e-learning solutions. At the same time, this heavily regulated industry has some unique requirements that must be met in order for e-learning to be used.

We're familiar with the features of e-learning. Some of these are of particular interest in the pharmaceutical industry because of the resulting benefits that include:

- Consistency of content and delivery;
- Availability 24/7;
- Availability from any location with a suitable inter-/intra-net access;
- Completing the program at the learner's own pace;
- Inclusion of text, audio, graphical, and video elements; and
- Rapid updates.

Examples of where e-learning is currently being used or implemented include providing:

- Basic regulatory training for personnel working in blood collection centers across the U.S. including large cities as well as very small/remote communities.
- Initial training to temporary workers or contractors.
- Intermediate-level training on how regulations apply in particular jobs.
- Basic and intermediate-level training to clinical investigators and institutional review boards on how to protect people who volunteer to participate in clinical research.

Regulations, requirements, and expectations

Most industries or sectors consider themselves "special" or "unique". Those of us in the pharmaceutical industry certainly do – in part because we are the most heavily regulated in the world along with the aviation and nuclear power industries. Drug agency inspectors, like those from the Canadian Health Products and Food Branch and the US' Food and Drug Administration, conduct periodic inspections, evaluating the quality systems, buildings and facilities, and manufacturing and laboratory operations. Training is a key element in each of these areas. The set of knowledge and skills these personnel need to know and apply is called, "Good Manufacturing Practice" or GMP.

Most countries or regions have their own set of these GMP requirements; most of the principles of GMP are the same from country to country, however there are some small differences.

Regulatory requirements are derived not only from what is published as regulations, but also from guidance documents, and best of industry practices that are "feasible and valuable" – a phrase of particular importance with the US FDA. Sometimes these requirements are referred to as "expectations" – which is what the regulatory agencies expect to see implemented by drug manufacturers.

Currently, there are three important expectations related to training of personnel using e-learning solutions:

1. Use of electronic records and electronic signatures that are at least as reliable and trustworthy as their traditional paper or hand-written counterparts.
2. Validation of computerized systems and applications to ensure they function as intended.
3. Assessment of personnel to ensure they have the required knowledge and can (and are) performing their assigned tasks as required.

The first two expectations must be considered as part of the design, development, and implementation of any learning management system or LMS and the e-learning "engine"; the second and third expectations must be considered in the design, development, and implementation of the specific training course applications. These expectations apply to e-learning projects done by contractors/vendors or by pharmaceutical firms themselves.

Electronic records and electronic signatures

In March 1997, the US FDA published a regulation, "21 CFR Part 11" (FDA 1997) that mandates that whenever electronic documents or an electronic signatures are generated or used to meet an FDA requirement, that they be created, stored, and retrieved in a way that assures their veracity – i.e., their truthfulness and reliability. The FDA had, in isolated but significant situations, discovered firms that had prepared and submitted fraudulent paper documents. The agency was concerned that by using computer technology, those firms intent on committing fraud could do illegal things, faster.

Regulatory agencies in other countries and regions have similar concerns but have not yet established such detailed requirements.

We all saw – or participated in – the work required to make computer systems Y-2-K compliant. For firms regulated by the FDA, Y-2-K was, without exaggeration, a fraction of the effort and expense to achieve "Part 11" compliance. Terms like audit trails, biometric and non-biometric signatures, certifications, and metadata are now part of our lexicon.

Neither the FDA nor the industry had a clear understanding of enormous impact of the regulation when it was published. We are still in a dynamic situation with the FDA as their expectations evolve.

Related to e-learning, Part 11 impacts learning management systems and any e-learning application that creates or stores records or requires someone to "sign" that they have completed a specified action. For example, if an LMS collects and retains assessment results from a learner's session and retains a record of this, an FDA investigator (or an in-house regulatory compliance auditor) could ask simple questions, such as: *"How do you know that this training record for Mr. G. Brown hasn't been modified in any way? How do you know that this is the actual data or record that was generated during the training session? Prove it to me."* Providing suitable – compliant – answers to these questions is the essence of Part 11.

Validation

Another question that regulatory investigators (and auditors) ask is, *"How do you know that this computer system or web-based training program is doing what it is supposed to do?"* That is the basic question answered through the process of validation. Validation is simply defined as having documented evidence that a computerized system is consistently performing as it was intended.

For new systems or applications that are being created, hardware and software designers utilize the "system life cycle" with defined actions and responsibilities that apply to both the system owner and the developer (or supplier). This approach is not unique to the pharmaceutical industry; the expectations are consistent with ISO standard ISO 9000-3 and recommended practices by the IEEE.

The nine phases are not necessarily a linear path; some are predicated on others being completed while at other times, there may be a re-iterative loop or branch that is appropriate to take. The phases consist of:

1. System idea (including a needs analysis report and a request for proposal [RFP])
2. System plan (defining user requirements specifications [URS] and system requirements specifications [SRS])
3. Design (producing the system design description)
4. Build
5. Test (verifying compliance to the system design)
6. Commission (system acceptance, validation to URS and SRS)
7. Operate
8. Maintain
9. Retire (decommissioning and retiring)

In other words, you:

- Define what must be achieved
- Produce a solution that achieves the goal
- Prove that the goal is being achieved
- Maintain control to ensure that the goal is achieved

Throughout this process, records become the evidence that the activities were done. Pharmaceutical client firms conduct audits of vendors to review the records and assure that procedures are written and are being followed to adequately control the entire process.

Accomplishing some of these activities is consistent with good instructional systems design or ISD practice, while other activities can be a challenge to control. For example, at Learnwright, as we have created web-based GMP training courses, we have been challenged to initiate and follow new rules of practice to comply with validation and change control when developing new programs or making fixes or changes. Key in this is having the proposed change approved, documenting what we are doing, and then adequately testing to assure ourselves and our clients that there have not been any unintended surprises. For creative software developers and ISD professionals, achieving this needed level of control is a discipline that must be developed.

Does this control take more time and energy? Yes. Does it cost more money upfront in the design and development process? Yes. Are there benefits to our clients and to us? Yes – it helps them meet regulatory requirements and helps us have a higher level of comfort that our courseware will work. It is an investment that we can make that builds quality and excellence into what we do.

Is all of this really necessary? Read the article in the July/August 2002 issue *of Technology Review*, entitled "Why Software is So Bad" (Mann 2002). You'll see how inadequate control during design, programming, and testing can result in serious problems.

Am I saying that learning management systems and e-learning courseware have to be developed and validated to the same degree that an implantable pacemaker must be? No. The key is that what we do must ensure that the e-learning solutions we provide are fit for their intended use – a basic definition of quality.

The third regulatory expectation that we mentioned earlier, *Assessment of personnel to ensure they have the required knowledge and can (and are) performing their assigned tasks as required,* is where e-learning technologies can have a unique impact. This is where we, as designers and producers of e-learning can leverage our creativity and engineering skills.

Assessing the learners

Those who have studied the theory of learning and assessment have confirmed a rather intuitive fact: The closer the design of an assessment exercise is to how the job is actually performed, the more confidence we can have that if a person does well on the assessment, the higher the probability that a person can transfer the knowledge and skill into the job. Yes, there are any number of factors that can block transfer, but with that said, the closer the assessment tool is to the job, the better.

A simple example: You are teaching me how to put on a sterile gown – we call them "bunny suits" – so I can working in an aseptic facility making injectable drugs like antibiotics or insulin. You give me a pen and paper test about the sequence of what part of the gown to put on first, second, third, and so on – I'll probably pass. I'm good at that type of fact recall. But my passing that assessment isn't going to tell you much about how I put on that gown – can I put it on in the correct sequence without contaminating it. For that, you want an assessment that is more of a simulation of how the task is actually performed in as close to the "natural" setting as possible.

With that in mind, I would like to show you three examples of how we at Learnwright have attempted to make our assessment strategy as close as possible to how a person in a pharmaceutical or blood products organization would apply certain GMP principles. These are what we call:

- Audit document
- Audit cam
- Audit conversation

The basic premise is that we assign the learner to examine something that they would have familiarity with in their jobs: they are to review documents, watch a person perform a task, and observe a conversation. It each situation, they identify deficiencies (based on other information and content provided or that they should know) and then determine the impact of the problem, state why it is a problem, or select the corrective action that is appropriate. These skills are similar to what an auditor would do during a GMP compliance audit. Hence the term, "audit cam".

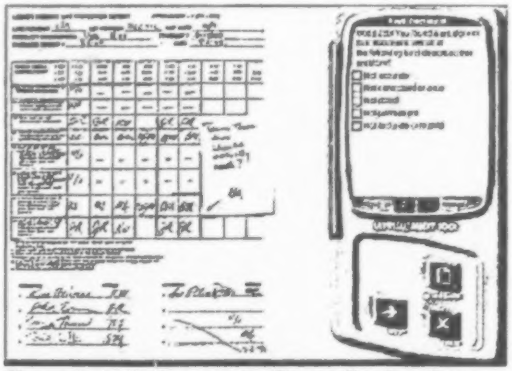

Figure 1. Audit Document – Data collection sheet.

BEST COPY AVAILABLE

An audit document is shown in Figure 1. The learner can roll over the document and see that different areas are highlighted. Some are real problems, others are distractors. The system deducts points for incorrect selections. So, if you know the information and select the correct hot spots and answer the follow-up questions correctly, you will keep a high score. If you guess, you will be loosing points, reducing the score.

In this audit document, you can see that a simple horizontal line is used to show that data is not present. In our industry, that is a problem – it should have an "NA" or a "not applicable" marking and include the writer's initials and date written. Clicking on that highlighted zone, I get feedback that I have found a valid problem and then a follow-up question that I need to respond to.

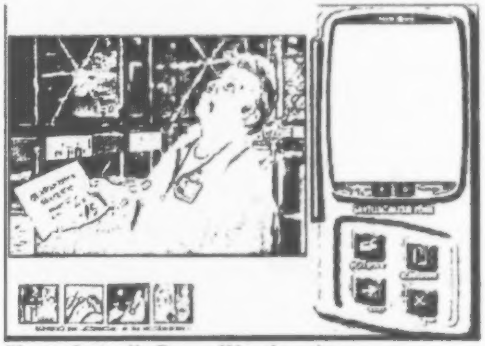

Figure 2. Audit Cam – Warehousing.

An audit cam is shown in Figure 2. The learner first reads a description of a video scenario that they will view – in this case, someone who finds a special "quarantine" label on the floor of the warehouse. Then they will view a 45 to 75 second video of the person doing the task, similar to what they do in their job. A voice-over presents what the person in the video is thinking as he or she performs the job. After completing the video sequence (which they can review without penalty), still-frames from the video are presented that include the problems visually depicted in the video. Here the learner plays the game, 'what's wrong with this picture' – identifying problems and determining their impact. Some of these video segments are "over the top" – most experienced personnel seeing these are on the floor laughing about the poor practices. That's fine – it opens up a part of their mind to the learning process and allows them, through the follow-up questions, to demonstrate that they understand *why* it is a problem or *how* they should properly respond.

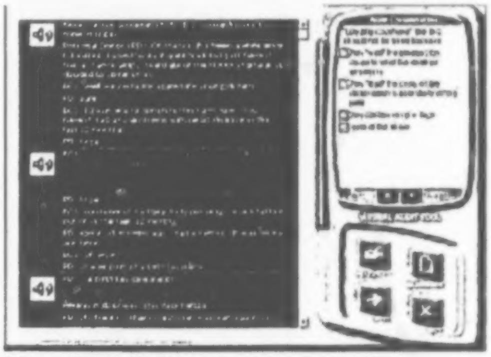

Figure 3. Audit Conversation – Transcript.

An audit conversation is shown in Figure 3. This was first developed because of the needs in the blood industry. If you donate blood, a screener must ask certain questions, in a particular way, in a proper setting. Using audit conversation, the learner will watch and listen to a videotaped conversation and then examine a transcript of that

BEST COPY AVAILABLE

conversation. The transcript has sections that are "hot" – again with the distractors and true problems – that the learner can click on. If a problem is found, feedback is given and a follow-up question is asked.

Since all of the scenarios used in the audit documents, audit cams, and audit conversations are based on real-life situations and problems that a person working in that area could reasonably encounter, these are almost simulations that assess the learner's ability to apply GMP knowledge and decision-making skills.

Conclusion

There are some special requirements in providing e-learning solutions to the pharmaceutical industry: electronic records and signatures, validation, and the need for assessment. Our experience has been that by embracing these requirements, our end product is more stable, controlled, robust, and focused on the true learning and compliance needs of our clients.

The Open Source Movement, Publishing, and the Dissemination of Knowledge

Bob Young, CEO – Lulu, Inc.

Summary

Content…. movies, music, books – it all falls under the rubric of "intellectual property". Indeed, this is only a subset of IP, but for our purposes it is a representative example. Here is the key issue to ponder: A series of changes in intellectual property law over the last 30 years has made it more difficult for researchers, scientists, authors, and artists to cooperate and collaborate on critically important projects. At the same time the advance of communications technologies, specifically the Internet, promises to foster an explosion in creativity, cooperation, and collaboration never before thought possible. How can the restrictive environment of today's intellectual property laws, often exemplified by copyright, co-exist with society's overarching interest in this burgeoning advancement? Remember, society's interest is both crassly commercial and sympathetically benevolent.

These interests reflect pretty grand, yet seemingly contradictory goals. This discussion considers how new tools and strategies will enable content owners, whether authors or publishers, to control their works and retain the benefits provided by "scratching the self-interest itch" that often provides primary motivation. At the same time users of these works are enabled to derive maximum value from pre-existing art and knowledge by building on these advances. They can, as Newton put it, "stand on the shoulders of giants".

Copyright: Yesterday, Today, and Tomorrow

What is copyright? How did it come into being? Quite simply, copyright began in the 16th century as a means for one group of printers to protect their printed works from being pirated by other printers. You see, that first group of printers had acquired permission from an "author" to reproduce a work, in this case, a book. Copyright was established as a protection for the work of that "permissioned" group of printers. In the United States, the genesis of copyright law is found in the Constitution, article 1, section 8, which states:

[The Congress shall have power] "To promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries;"

The original period of copyright protection was 14 years with "privilege of renewal" for an additional 14 years. Over the years copyright term has been extended repeatedly as the "fair use" rights have been diminished. While a smaller and smaller group may have benefited, an ever increasingly larger group has suffered. That group can easily be described as "society as a whole".

Copyright did not attempt to stop users from reselling a book, teaching from a book, quoting portions of the book, or using the book as the basis for satire or inspiration. Attempts to prevent a work like "The Wind Done Gone" from being published would have been laughed out of court. Today copyright lawyers would have you believe that it is almost no longer permissible to base any work on a prior work or on "that which has come before". For example, Walt Disney's practice of basing stories or characters on those that can be traced back to the Brothers Grimm (Snow White, for example) can now be interpreted as expressly prohibited. If we believe the lawyers, certain historical figures are, or will soon be, off limits to almost anyone creating works of art or fiction. Examples of this include Pocahontas and even Dr. Martin Luther King. This begs the question, "How does this benefit anybody"? Does Disney really have a claim to the Pocahontas legacy? Who owns the history of and the ideals personified by Dr. King?

Let me go out on a limb and predict that the pendulum has swung as far as it can on the issue of extending copyright regulations in favor of the big corporate content empires. There is a pending Supreme Court case called Eldred v. Ashcroft that is attempting to return a modicum of sanity to portions of the intellectual property arena. If not the Eldred case (www.eldred.cc) then some other, stronger case will likely begin to roll back these over-extended corporate rights. The crazy part about this entire scenario is that content companies like publishers, movie studios, and record companies ultimately have such significant prospects for gain. Fear of change, however, seems to keep them blinded to this new world of opportunity.

What does this actually mean to an industry like publishing? It means significantly less than many of the conglomerates fear. First of all, most publishers do not make any money on content that is over 90 years old. Most earn the vast majority of their revenues on content created in the last five years. Indeed, an ability to use their marketing and editorial engines to leverage an enhanced public domain would become a powerful tool in their business toolbox.

At any rate, it will serve to focus the concentration of the leaders of this industry on the recognition that they earn their money not by forcing their customers to buy their products, but by delivering such high value goods and services that customers are pleased to buy them.

The Future of the Internet and Why We Can't Count Out eBooks

Despite all the dire predictions for the Internet and how it would certainly fall prey to one evil monopoly or another, the future is going to look much like its recent past. It will continue its rapid growth in both access and speed. The Internet is becoming as ubiquitous as television. That will not stop. It is also well on its way towards becoming more ubiquitous than the telephone is today. For businesses like the publishing industry, the meaning of this ascent will either be terrifying or thrilling, depending on its state of readiness. Rapid change in technology is wonderful....especially if the real users of that technology think so.

Many of us, myself included, have had great fun pointing out fatal flaws with eBook technologies. This was even more fun given the fanfare that accompanied eBooks and their proponents. In direct opposition to the initial hoopla, one might now assume it is a given that the average pleasure reader will never read electronically displayed text. We are becoming convinced that humans prefer the tactile sense of holding an organic material like paper and the "always-on" convenience of the printed page.

Don't kid yourselves! The ridiculously creative, competitive, and wealthy technology sector prides itself on making its own technology offerings obsolete every 18 months or so. It may take them 20 more years than they predicted. However, they will get the technology application right. When that happens the electronic sharing and collaborative development of content will become more commonplace than email. The benefits, commercially and societally, will be astonishing.

Remember the paperless office predicted in the '70s? Well it is almost here, admittedly 30 years late, but for many firms it will soon be their reality. Remember the Apple Newton personal organizer of 1990? It failed spectacularly, only to reappear as the hugely successful Palm Pilot. This is a prime example of better engineering and better technology that was "based on what had come before".

Every eBook I've tried to read has been....how can I say this nicely....a challenge. What the heck, they've all been duds. It may take three years or it may take 20, but someday the eBook, or some of its progeny, will build the business that obsolesces the companies who currently make their living putting ink on dead trees.

As the Internet becomes more "everywhere, all the time", at even lower cost, most consumers will prefer to "read" or "experience" content electronically. All of us – business people, educators, and learners – better be ready or we will look like the proverbial buggy whip manufacturer, the horse and buggy driver, or the uncomfortable horse and buggy passenger when Henry Ford came along and put a Model "T" in every garage.

Future Partnerships between Authors, Publishers, and Consumers

How do all the players take those first small steps into this brave new world? There are a few "watch words"; let me suggest just a couple and then propose a couple of additional "rules". First, we should all consider the concept of trust. As in, "I trust you to do what you said you would....and what I said you could." This "one on one" relationship will become even more critical as technology advances. The "barter" relationship of the Open Source movement depends on this type of trust. Again, the opportunities for existing, large, commercial entities to benefit from their existing positions could be huge. All they have to do is secure (or retain) our trust. Second, we should all consider the benefits from the word "extend" – like "I extend to you the right to....(fill in the blank). Better yet, how about, "I extend to you the right to improve on my work."? Just don't forget to "cut me in" – monetarily or recognition-wise.

Here are two rules that I would suggest hold true for large commercial enterprises as well as research-oriented organizations and institutions:

1. Experiment, experiment, experiment. Many small inexpensive initiatives will beat a very large well-funded R&D project every time. Play to your strengths. In business and in education it is essential to partner with good partners. While this seems self-evident it is often simple truths such as these that are ignored. This is where an Open Source perspective comes in. The ability to benefit from your partner's work and experimentation is critical to moving forward both your initiatives and your partner's goals. As an aside, many of you may have been waiting for me to insist that "a key to the intellectual property business castle" can be had by giving away copyright-protected content (whether on your own or on your author's behalf). I hate to disappoint but that would seem like a clueless thing to do unless you can find good commercial reasons for doing so. Of course one reason to "give away" content is to receive something that you want in return – the barter analogy.

These reasons might include, for example, trying to build a readership of related materials that your enterprise sells, or trying to build a reputation of or a following for a particular author, artist, or project. In general, Open Sourcing (or giving away) previously copyright protected content may not earn you direct revenue but it certainly could serve to reduce marketing or other costs associated with development or generating revenue on related materials.

But this is somewhat of a digression. The real importance of Open Source is your selection of partners, especially technology partners. What Open Source can mean to you is that you actually gain control over the technology you will use to distribute content in this new world just described. This potentially puts one in the position of controlling how content can be used (from a publishing perspective, for example) while becoming unshackled from any dictates a particular technology provider might want to impose. Open Source strategies ultimately put those controls in the hands of the full range of users. Exploring this from an integrated technology and content perspective could lead to a content owner establishing relatively non-restrictive licenses on how the content can be used in other publications while imposing no restrictions with regard to delivery mechanisms.

Open Source software is simply a real, verifiable, and guaranteed commitment on the part of your technology supplier to treat you like a partner with regard to the use of that technology. This is critical because when technology is used to reach your customers, you or your organization retain control over customer access and you do not become a victim of that supplier.

2. Don't fear your customer. Your customers may not always be right, but they are always your customers. Your customers want a level of control, they need this control, and they will pay for control. This is especially true if you are a content provider. It can easily be deduced that the record industry, based on their public pronouncements, apparently must fear their customers. They are seemingly convinced that most of their

customers are crooks and draconian new laws are needed to protect this industry from these "customers". What a sad way to live you life! What a stupid way to serve your customers! You can treat customers badly for a while, sometimes even for years, but it always comes back to haunt you. Either the customers will find a way to avoid your product or service altogether (think using email rather than going to the post office), or they will migrate en mass to a new supplier who treats them like....well....customers (think Wal-Mart versus Kmart).

Don't let the public relations barrage from lawyers representing large "content conglomerates" fool you either. Extracting never-ending and ever increasing revenues on existing content libraries without offering similarly increasing benefits to customers just will not happen. Ok, it may happen for a few, well-developed consumer icons like a mouse with big ears....but for the rest of us....and them, the old rules still apply. Content businesses will make most of their revenues the old-fashioned way. They will earn them by providing better, more useful and valuable content to their customers than their competitors. Best of all, this can be provided in formats that make content more useful, accessible, and/or entertaining.

Try new things. Get close to your "consumer". Trust this brave new world and extend opportunities for others to enhance your work. As we move forward I hope that control of intellectual property remains in the hands of its owners and developers. However, I truly believe we all benefit if a full array of rights and permissions are granted so that others can build on the pre-existing base of knowledge. I think this will lead to more flexible, learner-centered customizations in the education arena. Best of all I feel that we all can benefit from the lower costs of an electronic delivery model and the added value of dynamic content.

Abstract: This study sought to analyze the technical problems encountered by students in a technology training course for educators. The results of the study then informed the redesign of the course for its next offering. The study collected data by both qualitative and quantitative means with the overall purpose of determining in which course modules the students encountered the most technical problems. Further data collected from the survey following the course indicated that occurrence of technical problems did not negatively impact the students' rating of the value of each module or the perceptions of the value of the course.

Introduction

This paper reviews the results of a web-based course intended to teach technology skills to practicing K-12 educators. While computer-based training has long been used for training technology, new systems being developed for online courses will benefit from continued research into the practice and application of Internet technology in distance education situations. The American Federation of Teachers recommends "as we encourage experimentation in distance education, we must conduct much more rigorous evaluation of distance education programs" (p.15).

The purpose of this study was to begin an evaluation process to meet those needs. The development of this course follows a four stage process of (a) Design, (b) Development, (c) Evaluation, and (d) Revision (Willis, 1992). At the point that this paper was written, the course was undergoing the evaluation stage of the course development process. The results from the data gathered will serve to inform the course designers during the revision stage of the process.

Relevant Literature

In 1995, the Office of Technology Assessment identified technical problems as one of several barriers to technology integration in the K-12 educational practices. The Institute for Higher Education Policy (2000) identifies reliability of distance delivery system is also a benchmark for quality online education.

Technical problems while using computer technology are certainly not an uncommon occurrence. Harmes (2001) notes that in a case study on a internet based course, "the most frustrating portions of the distance learning course were reported to be problems with software (e.g. using AOL's browser), trouble communicating with other students, and long download times" (p. 2854). Other studies have indicated that only 20.9% of course websites have technical help functions available (Mioduser, et al., 2000).

It is possible, however, to alleviate some of the technical problems that might be encountered in online courses. The development of a course website is very similar to the development of other software. In this study, the "software" being developed was the course website, tutorial modules, and assignments. Mishra (1999) proposes that the design of software "is an ongoing conversation" (p. 231). This conversation includes the initial design of software, testing the software, presenting to clients, and other reiterative processes used to develop and refine software to meet the specified need. In terms of online courses, the clients include both the instructor and the students, thus consideration must be made for the usability needs of both the instructors and the students

Even with careful planning, testing, etc., there is still a high likelihood that inconsistencies in web browser software will impact a web-based course (Horton, p.115). Because of such things as browser inconsistencies and the multitude of differing computer configurations, it is nearly impossible to test a web site for a course in every possible configuration, it is even less possible to test software to be used in a course for every possible situation that might be encountered.

Undoubtedly, there are some technical problems expected when teaching a course on technology with technology. It is the ultimate goal of internet-based educational systems to be as free from technical problems as can be reasonably expected and to provide timely and appropriate assistance when a problem occurs.

Course Description

The topics covered in the course were a concepts relating to computer operating systems, the Internet, digital image manipulation, digital cameras, QuickTime Virtual Reality authoring, and the introduction of a custom-built website for sharing electronic images and files. There were a total of six major course topics, each with a tutorial module and an assignment to be completed by the participants after working through the tutorial module.

The course was taught by the first and second author of this paper, both of whom had previous experience designing and teaching educational technology courses at the university level in a classroom setting, at a distance via the Internet, and also in training workshops with practicing educators on the topics presented in the course.

During the course, the primary means of communication between the students and the instructors was through of email. The course website featured a form that would send email to both instructors and also the email addresses of both instructors was given on the course website. Students were encouraged to contact the instructors via email if they had any questions, problems, or other needed other assistance.

Assignments in the course were submitted via web-based forms, or alternatively as an attachment to an email message. Of the six assignments that were required in the course, two were primarily text-based information, three assignments required uploading one or more files that were then delivered to the instructors, and the final assignment was to based on the students' ability to successfully use an web-based application for media and file sharing (hereafter referred to as the "Artifact Archive").

Participants

This course was part of a series of online courses and workshops for the teachers involved in a Technology Innovation Challenge Grant program funded by the US Department of Education. Prior to this course, the participants had taken two online courses which used a similar interface and similar course features and attended one three-day workshop, and one two-week workshop involving technology training. There were a total of 51 participants representing 17 school districts in 9 states in the course for the eight week session.

Methodology

The evaluation of this course used two primary sources of information. First, because email was the primary means of communication between students and the instructors, all email communication between students and the instructors was collected. After the course was completed, participants then completed a 67-item course survey that covered multiple aspects of the course. For the purpose of this study, items relating to technical problems encountered and the core content of the course were extracted from the survey data for analysis.

Analysis of Survey Data

The 67-item survey administered following the completion of the course provided information on different aspects of the course, including technical problems encountered. Other information on the survey was not relevant to this study, but will inform other aspects of the course development. The primary items analyzed were the items pertaining to the course tutorial modules and the general course evaluation questions. The tutorial module items asked the participants to rate themselves on their proficiency with the topic before and after the course. The participants were also asked to rate the level of difficulty of each tutorial module and associated assignment, the amount of help needed to complete the module and assignment, and the possibility of using these modules in their classroom. In a following section of the survey, the participants were asked to indicate which modules they found most valuable, least valuable, and which modules they would suggest included in future versions of this course.

From the available survey data, the ratings of "level of difficulty" and "help required" were selected as primary indicators of possible modules where technical problems factored into the success of the course. Also, the indication of which course topics were most valuable, least valuable, and should be included in future version of the course were also examined to further indicate which course topics were most problematic because of technical difficulties. These data would provide initial findings to be confirmed by the analysis of the electronic communications from the course. Additional information was also provided by the survey in the form of comments from the participants. This information was reviewed and used to gauge the overall response of the participants to the course.

Analysis of Email

A coding scheme was developed after the completion of the course to analyze the content of the email messages. Table 1 lists the three levels of coding that were used in the analysis of email messages.

Table 1

Coding Scheme for Participant Email Messages		
Level 1: Message Type	Level 2: Course Topic	Level 3: Detail
▪ Problem ▪ Question ▪ Comment ▪ Other	▪ Operating Systems module ▪ Internet Module ▪ Digital Camera Module ▪ Graphics/Image manipulation module ▪ QuickTime VR module ▪ Artifact Archive module ▪ Multiple modules ▪ General/Other	▪ Submitting Assignment ▪ Using/Installing software ▪ Course administrative ▪ Regarding assignment ▪ Regarding ▪ grade/completion ▪ Website Issue ▪ Other

Following the coding of the electronic communication, the analysis was conducted to examine the messages according to the Level 1 groupings. After determining the total number of problems, the messages were then further sorted by the course topic to which they messages were related. This provided information about which course topics seemed to cause the most problems and which course topics caused the fewest. Following the second level categories, the messages were further sorted according to the details of the type of problem encountered. This information provided insight into how the problem might be avoided or corrected in future iterations of the web-based course.

Findings

Level of Difficulty

In assessing the level of difficulty of the course topics, the survey data indicated that the Operating Systems, Internet, and Digital Camera course topics were rated at a low level of difficulty. For each of those course topics, nearly 60% or more of the course participants rated those topics as a 1 or 2 level of difficulty on a 5 point scale, with 1 being not difficult at all and 5 being very difficult. Specifically, for the operating systems, Internet, and Digital Camera modules, 59.5%, 63.6%, and 67.4% respectively rated those modules as a 1 or 2 level of difficulty.

Conversely, the graphics/image manipulation (Mean = 2.36) and the QuickTime VR (Mean = 2.95) course topics had higher ratings for difficulty. Though none of the mean ratings appear drastically higher or lower than the others, the data indicated that none of the participants rated the Internet, Digital Camera, and Artifact Archive topics at the "very difficult" level. The QuickTimeVR topic had the highest percentage of "very difficult" ratings with 11.4% of the participants and also the highest percentage of ratings of a 4 (25.0%).

Help required

In analyzing the data regarding the amount of help required to complete each course topic, the survey data indicated that the QuickTime VR (Mean = 2.93) and the Graphics/Image Manipulation (Mean = 2.37) course topics ranked highest on a five point rating and the Operating Systems (Mean = 1.86) and Internet/Web Browsing (Mean = 1.69) topics ranked lowest.

Most/Least Valuable topics and Suggestions for future revisions

The third area that was selected as a possible indicator for technical problems was the survey data concerning the most and least valuable course topics and the suggestion for topics to be included in future versions of the course. From the data collected, the QuickTime VR topic ranked highest as the most valuable course topic, followed by the Graphics/Image manipulation and the digital camera topics. The data indicates that the Operating systems topic was the least valuable, followed by the Internet topic. Also, the QuickTime VR, Graphics/Image manipulation, and digital camera topics all were suggested for inclusion in future versions of the course by more than 90% of the respondents.

Results of Analysis of Electronic Communications

During the course, a total of 121 email messages were received that were communication from the course participants to the instructors regarding the course. Since email was also an alternative delivery method for the assignments, those email messages were not considered communication, but rather assignment submissions. Of those messages received, 49 (40.5%) were reporting an instance of a problem encountered while completing the course topics or assignments.

Fifty-one percent of the problems occurred either installing or using the software being taught in the course topics. Also of note is the 28.5% of the problems reported were encountered while submitting an assignment. In looking at those two types of problems that accounted for 79.6% of the total problems reported, it can be seen that 68% of the software installation or use problems were encountered when completing the QuickTime VR topic while the problems while submitting assignments were encountered most with the digital cameras (28.6%) and the artifact archive (42.9%).

Discussion of Results

Perhaps one of the most interesting comparisons of results is that of the number of technical problems reported seemed to have a less significant impact on the suggestions for inclusion in future versions of the course than expected. For example, the number of technical problems with the Operating Systems and Internet course topics were low; the operating systems tutorial and assignment had only two reported technical problems, while the Internet tutorial and assignment had no problems reported. However, the Operating Systems topic ranked lowest on the suggestion for inclusion in future versions of the course and highest as the least valuable course topic. The Internet topic ranked 4 out of 6 on inclusion in future versions of the course and second as the least valuable topic. The QuickTime VR topic had the most problems reported, but ranked highest for inclusion in future versions of the course.

Other results of interest include the relatively high number of problems while submitting assignments via the course website. Since assignments in this course were primarily submitted via the course website, the problems encountered are a point to be carefully considered.

Conclusions

From the data collected, the overall response to the course topics was positive. Many of the surveys included positive comments regarding the course and no negative comments regarding the course overall were encountered. With regard to technical problems encountered, some conclusions can be made regarding which modules were most problematic and the types of problems that were most common.

The data indicate that the QuickTime VR topic had significant problems with the software used and made available to the participants. Most of the problems encountered in the QuickTime VR topic were related to the software not working properly in some fashion. In many cases reported, this problem was a result of compatibility issues with various computer systems on which it base being used.

The Artifact Archive topic also had significant problems, though no strong common link between the problems seemed apparent. Most of the problems were unable to be replicated or only occurred once. Given that the artifact archive is a web-based file sharing application, it is likely that problems were due to communication issues between the users' computers and the server on which the application was hosted.

A third problem area was in submitting assignments via the course website. Problems reported, other than those in the Artifact Archive, were mostly in completing the digital camera assignment and were reported as uploading errors. The most likely cause of this problem is that the assignment required an upload of several files, some of which were larger files that required a longer time to upload, which can often exceed the time limit for uploading files to the server due to low bandwidth connections.

Implications

This study indicates that there are several improvements that can be made to the course itself to alleviate some of the technical problems encountered. These improvements include procedural improvements for submitting assignments, the choice of software for particular topics, the inclusion or exclusion of some topics in future versions of the course, as well as adjustments to be made to the course to accommodate the various levels of competency in technology encountered.

Procedural improvements to the course will primarily impact the submission of assignments. Over the duration of the course, several problems were encountered submitting assignments. This was most often remedied by asking the participants to submit the assignment files as an attachment to an email message to the instructor. The most likely solution to the problem of assignment submissions is to have all assignments submitted in this fashion where file uploading is necessary. No problems were reported that indicate a problem submitting an assignment as an attachment to an email message. In one case, the email message that was reporting the problem also included the files that were being submitted. To that participant, attaching the files to an email message seemed the best solution without any suggestion from the instructors. In all other cases, attaching the files to an email message was a successful remedy to the problem when suggested by one of the instructors. For that reason, assignments in future versions of the course will be submitted as an attachment to an email message, with the submission via the website remaining available as a backup option for students who might not have access to their email. In cases where uploading via the website is required, the web pages that manage the upload will be arranged to limit the number and size of files that can be uploaded to more appropriate limits to alleviate the problems such as upload script timeouts.

In choosing software to be used in the course for the completion of the tutorials and the assignments, careful consideration must be made to ensure that software is available to all participants and that it is reliable. Clearly there were some pieces of software used that did not meet the essential requirements of stability and availability to be included in future versions of the course.

The survey data provides some compelling information when considering which topics in this version of the course should be included in future versions. According to the survey data, a large number of the participants recommend that the Operating systems and Internet sections be removed from the course. One of the follow-up questionnaires, however, mentions that the Operating Systems topic was necessary. Judging from additional information provided on the survey, it seems that the central issue with the Operating Systems topic and the Internet topic is that these covered basic skills that were already very familiar to the participants. The data concerning level of difficulty from the survey also seem to support that statement. From the instructor's perspective, however, and also supported by the ISTE Technology Standards for Teachers, these two topics are essential and must be available to those who do not have these skills and knowledge. Some of the subtopics in the Operating Systems topic in particular are seen by this author as ultimately valuable for any computer user. With all things considered, it is apparent that the participants in the course should ultimately have some choices in what topics they need to complete, based on their self-assessment of their skills and knowledge.

In general, the implications of the data collected are that the course needs revision to address some of the technical problems. Given the relatively low occurrence of technical problems, only 48 reports of problems, and the indications of the value of the topics covered, it would seem that the course met its overall goals of providing applicable and productive training in specific areas of technology despite the occurrence of some technical problems. Future versions of the course should clearly seek to avoid the technical problems that did occur while maintaining relevant topics and the ability to address the various skill levels of the participants.

E-Learning and Knowledge Management: the MEMORAe Project

Marie-Hélène Abel, Dominique Lenne, Omar Cissé

UMR CNRS 6599 Heudiasyc
Université de Technologie de Compiègne
France
{mhabel, dominique.lenne, omar.cisse}@hds.utc.fr

Abstract: e-learning leads to evolutions in the way of conceiving a course. Diffused through the web, the course content cannot be the pure transcription of a "classical" course. The students need to personalize it and to access it when they need it (just-in-time). Therefore the course content is often divided into knowledge grains. The MEMORAe project aims at applying knowledge management techniques to improve the structure of the content and its access in e-learning solutions. We propose to build an ontology based "learning organizational memory" and to give the users a direct access to this memory by using "knowledge books". The pilot application we chose is a course on algorithms and programming attended by beginner students in our technological university.

Introduction

Information Technology has already transformed the way we work and has a growing impact on the way we learn. New approaches mainly based on the utilization of web technologies are proposed. These approaches are often grouped under the concept of "e-learning", which is still unclear but often put forward as a key-solution to professional training difficulties. Indeed, e-learning allows on-site training and can contribute to a closer integration between working and learning situations. However it raises also many problems and its progression is slower than one could at first think.

A key point in building an e-learning solution is to give the users an easy access to the contents and to the resources they can use. To this end, knowledge is often cut up into grains (Boullier, 2001), joining in that knowledge management techniques. More generally our goal in the MEMORAe project is to study the possibility to apply knowledge management techniques to the construction of e-learning solutions. We propose to build an ontology based learning organizational memory and to make it available to students in an e-learning context.

As a pilot application, we chose a course on Algorithms and Programming, which is taught at the Technological University of Compiègne (France), in face-to-face as well as in distance education. Before describing this project in details, we first clarify our conception of e-learning and we argue for making the link between knowledge management and e-learning.

From Training to E-Learning

E-learning brings some new characteristics regarding to classical training situations. First of all, using the term e-learning rather than e-teaching sets the focus on the learner. In e-learning situations, the learner has to be more active than in classical training applications. Knowledge is not presented linearly as in a course. It is often divided into grains and the user has to choose the grains he considers as being useful for him. He can be helped in this task by a tutor. Teachers and learners roles are deeply modified: learners have to be more active and can cooperate with other learners, teachers play the role of tutor and have rather to assist students than to deliver their knowledge. The tutor pedagogy is based on the personal work of the student.

To sum up, we consider an e-learning application as being a distance learning application

- Using a network approach,
- Giving access to contents divided into grains and not to a linear course,

- In which students are active and can work in a collaborative way,
- In which teachers role is rather to assist students than to deliver their knowledge.

This definition puts the emphasis on the contents provided to students. It presupposes pedagogical resources to be precisely described in order to allow the students to easily access them, with the help of the tutor if needed. The contents elaboration is a quite complex and time-consuming operation that can rarely be realised by the only tutor. Moreover an e-learning application has to allow the management of all the relations, contents and technologies. It implies to identify the expertise in the course organisation itself.

Knowledge Management and E-Learning

In an e-learning application we find people (learners, teachers, administrators, etc.) who need to communicate and to access knowledge and information when they need it ("just in time"). This kind of situation has some similarities with a knowledge management situation.

Knowledge management aims at formalizing knowledge in order to share it and to reuse it. The process of knowledge management involves the following actions (Benjamins et al., 1998):

- gathering the knowledge to be managed,
- organizing and structuring the knowledge,
- maintaining knowledge,
- bringing the knowledge to the persons who need it.

A way to fulfill these requirements is to conceive a corporate memory or more widely an organisational memory. Following (Barthès et al., 1999) an organizational memory is an explicit and persistent representation of knowledge and information in an organization, in order to facilitate their access and re-utilization by adequate members of the organization.

The implementation of an organizational memory may vary according to its expected utilization. It often uses a database, a knowledge base or a document indexing system. The design methods vary according to the available sources: human experts, paper or digital documents etc. A frequently adopted solution to design and manage an organizational memory is to use ontologies.

In knowledge engineering a commonly used definition of an ontology is the one of Grüber (1993): "an ontology is an explicit specification of a conceptualization". By "explicit specification", Gruber means that the ontology is coded with a language. This language can either be the natural language or a logical language.

Roughly an ontology can be represented as a hierarchy of concepts augmented by a definition of the relations between the concepts and by rules and constraints (Fortier, 2001).

In our project, the elaboration of an ontology will be useful to structure the learning contents and to define a shared vocabulary. The ontology will allow to add a context to the requests and to facilitate the access to the information thanks to the semantics associated to the concepts.

Learning Contents Management: the MEMORAe Project

The MEMORAe project focuses on the contents management in an e-learning application. We consider this issue as a knowledge management issue involving acquisition, gathering, organization, maintenance and distribution of the learning knowledge. We are building what we call a "learning organizational memory" (Fig. 1). Users (learners, teachers, tutors, etc.) have access to any capitalized information related to the course they have chosen: pedagogical objects (Bourda & Hélier, 2000), learning objects (Boullier, 2001), users descriptions, etc. Moreover they can communicate and collaborate through the memory. The memory is built and structured by the way of ontologies.

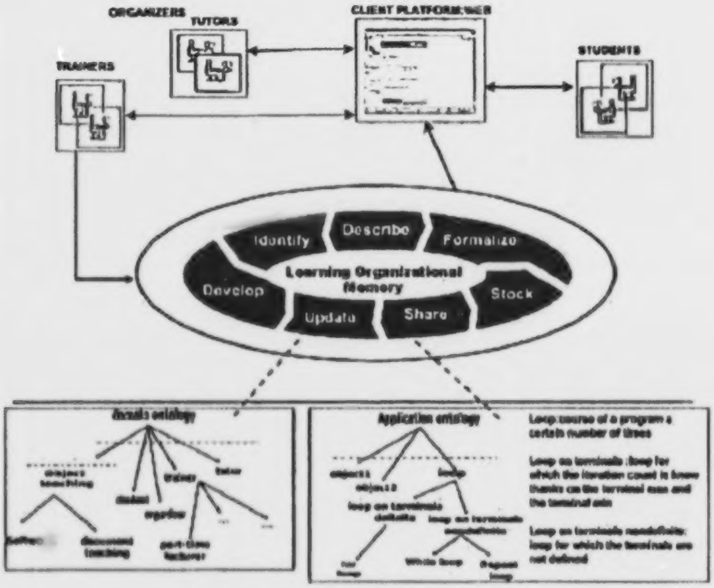

Figure 1: the MEMORAe Project.

We present below the course that we have chosen as a pilot application. We precise the distinction between learning objects and learning contents. Then we describe the learning organizational memory contents and structure. Finally, we explain how we materialize and diffuse this memory.

Choice of an Application : NF01

In the MEMORAe project, we consider scientific teaching at university. The pilot application we have chosen is a course attended by young students (first year at the technological university of Compiègne). This course, which is often referred to by its code NF01, is a course on "Algorithms and Programming", delivered in face-to-face education (250 students) as well as in distance education (25 students). This course combines theoretical and practical teaching. Its goal is not to learn Pascal programming but to learn programming itself. The Pascal language is only introduced to practice notions on algorithms.

Learning Objects and Learning Contents

Developing a course diffused through the internet implies to set the pedagogical focus on the student. The goal is to make him/her active, to give him/her a clear view of the available resources, and to learn him/her how to seek and use them. The articulation of a course around learning objects offers many learning individualization possibilities. According to Boullier (2001), such a division of the "knowledge world" is a preliminary act, needed in any teaching process. Boullier sees this division as materialized by the supports. Learning objects are the result of a delimitation of texts, a semantic marking up (Bachimont & Charlet, 1998). Contrary to this work, we do not consider a learning object as being a piece of a linear course text, but as a notion to be learnt. Thus, it is not necessary to build any support materializing such a delimitation. Authors remain free concerning the creation of their learning support, for example they do not have to follow any graphic charter. Learning objects (notions to be learnt) index documents related to them.

Within the framework of the MEMORAe project, we represent not only learning objects but also other types of knowledge such as documents and information related to these objects. Our choice of representing learning objects as notions (concepts) that allow to index documents related to them gives more flexibility to the writing of documents and allow the reuse of various types of documents. The fact that a learning object references many documents allows many ways to get it.

BEST COPY AVAILABLE

The course manager is responsible for the quality of the teaching content, he defines learning objects and selects documents to be indexed. Among learning objects, we can also find problem-situations (what to do in such situation ?). The tutor is in charge of the construction of the teaching scenario.

Content of a Learning Organizational Memory

A learning organizational memory allows to capitalize not only learning objects but also any knowledge, documents, information related to them. The organizational memory we build does not capitalize the whole documents and knowledge related to the NF01 learning objects but a pertinent part according to the course manager.

Beyond the pedagogical content, the memory capitalizes:

- Any information related to the learning environment that can be useful to users: trainers, staffs, entry form, learners, etc.
- Users knowledge.

Within the framework of e-learning, the student has to be active and to access to different types of information. The need of a shared vocabulary between the actors of the educational process is thus reinforced. In order to define this shared vocabulary within the memory, we propose to develop an ontology, more exactly several ontologies:

- A domain ontology of learning: it defines concepts of the learning domain, concepts which remain generic for this domain. In such an ontology we find for example concepts like: coach, tutor, secretary, as persons, or book, learning device as documents.
- An application ontology: it defines concepts of a particular application, and contains concepts definitions more specific than those of the domain ontology. For example, concerning an ontology about algorithms, concepts such as loop or array are defined. An application ontology has to be defined for each course considered. It's through this ontology that the learning objects are determined.

These ontologies are part of the organizational memory, in other words they structure it. In addition to them, the memory contains various documents related to the course. These documents are at least represented in the organizational memory, some of them are directly stored in the memory.

Materialization of a Learning Organizational Memory

Starting from the necessity to exploit the web to realize an e-learning application, we made the choice of materializing our organizational memory by the way of computing structures:

- a knowledge base to represent knowledge and receive ontologies,
- a documents base to store various electronic documents indexed by knowledge.

Diffusion of the Organizational Memory

The organizational memory we build consists in ontologies and electronic documents. The memory user has to interrogate concept representations to reach the needed information. In order to give him this possibility, we chose to use the concept of knowledge book (Ermine et al. 1996, Kassel et al. 2000, Abel et al. 2000) which represents a knowledge base consulting environment.

Navigating through a knowledge portal that is unknown is often a difficult task. If the portal is well structured, it is usually more helpful for the user to explore it by browsing (Staab & Maedche 2001).

The knowledge book is a document which allows to consult knowledge represented in a knowledge base. This book differs in several points from classical portals. On one hand, its content and its presentation are generated starting from the knowledge base. On the other hand, its structure is still the one of a classical book augmented of IT functionalities. According to Boullier (2001), the stability of the workspace constitute a cognitive framework, particularly useful when there is no interaction allowing to adapt one by one common marks like in a face-to-face teaching.

The knowledge book is an hypertextual document: links allow to navigate within different representations and to make actions relying on these representations, for example, reaching electronic documents of the memory or sending an email to a person.

The knowledge book consists in two frames (Fig. 2). The static left frame presents different parts of the book to the user. These parts concern the learning contents and are chosen by the course manager. The dynamic right frame displays the content of the selected part. These two frames allow to read the knowledge book in two ways: a "predefined way" and a "free way", with the possibility to shift from one to the other at any time.

is a loop

possesses a terminal min

possesses a terminal max

possesses an algorithmic syntax syntax-algo-1

possesses a Pascal syntax syntax-pascal-1

is approached in book B-1

Figure 2: a Knowledge Book.

The "predefined way" is made possible by the way of the left frame. Indeed, as in a traditional book, the user is guided by the structure of the book. The only difference is in the possibility to directly access the different parts of the book by using the mouse.

The "free way" consists in browsing through the ontology presented in the right frame. It gives the possibility to reach a given knowledge piece in different ways: by browsing through the hierarchy of concepts or by browsing through links between knowledge pieces in the memory (e. g. "Loop is approached in Book B1").

Electronic documents of the organizational memory are represented in the knowledge base as object models representing instances of concepts defined in the sub-ontology of documents. They are stored in a documents base. The knowledge book allows to diffuse objects models of the knowledge base (Fig. 2). Starting from the representation of these models, the users can reach stored electronic objects. Indeed, if the user wants to reach a document itself and not its representation, (s)he can do that by the way of a contextual menu that allows him/her to execute different actions on the knowledge representation, for example "reach an electronic document".

Thus, whatever the knowledge is, its access and presentation are always done in the same way. So, we obtain a coherence in knowledge presentation formats and users can find new handling ways.

BEST COPY AVAILABLE

Conclusion

We focused in this paper on content management in e-learning applications. We consider that it is a knowledge management issue involving acquisition, gathering, organization, maintenance and distribution of learning knowledge. We propose to design an ontology-based "learning organizational memory" that will be made available to the actors of the educational process. This memory capitalizes the notions students have to learn and all the needed related information. The knowledge grains representation relies on an ontology. These grains are used as an index to access various related documents and information.

By using ontologies, our goal is also to define a vocabulary common to all the actors involved in the learning process. This common vocabulary is particularly needed in a distance context. In the evaluation of the learning organizational memory we plan to make we will particularly examine to what extent this vocabulary can be shared by learners and tutors. Furthermore through our pilot application we will evaluate how the memory can help a student to build its own personalized course.

Abstract: This article describes a mobile learning project, where mobile devices are used for educational activities. The article defines the word "mobility" from the educational point of view. We present experiences recorded while using mobile technology in teacher training and among students of forest resource. Two pilots were carried out at the Department of Home Economics and Craft Science and the Department of Forest Resource Management of the University of Helsinki. The idea of the pilot in home economics teacher training was that supervising teachers and trainee students should discuss and share their ideas about teaching methods etc. through mobile devices and also using SMS-messaging and digital pictures as part of the supervising process. The use of digital pictures which were delivered via the mobile device was surprisingly successful. The students of forest resources used mobile technology to deliver textual and pictorial material from forests. The goal of these innovative pilot projects is to create flexible teaching solutions, which will enable users of all kinds of devices to access of information, and to support learning in a variety of situations.

Introduction

According to Clark Quinn (Quinn 2000) "Mobile learning is learning through mobile computational devices". So mobile learning refers to situations in which students use mobile technology in their studies. Characteristic of mobile learning is the opportunity to break away from the teaching that takes place in a classroom, and to move to another location while communicating over information networks. Another distinctive feature of mobile learning is that it enables learners to enter an information network at the precise moment when it is necessary by using a portable learning device and a wireless network. Mobile learning may be considered as an extreme form of flexible learning. The mobile environment integrates studies that take place on campuses, at homes or outside university facilities into one shared, flexible learning environment (Sariola 2001).

The university of Helsinki has had a special interest in trying to benefit from the use of mobile technology in learning and teaching. One of the reasons is that the university itself is changing from a traditional monolithic, integrated unit to one with four different university campus areas, which are physically located in different places. This brings a need for mobility and flexibility. This in turn often means solutions which use mobile technology. At present, Finland has about 5 million inhabitants, over 70% of whom have mobile phones. Approximately 98% of university students have a mobile phone, so we can assume that university students are highly experienced users of mobile technology (Tuononen & Helin 2001).

Since the middle of the 90's several teachers and researches at the University of Helsinki have experimented mobile technology in teaching and studying. The first project was the LIVE –project (Learning in a Virtual Environment) in 1997-1999 (see Nummi et al. 1998, Sariola et a. 2001). The UniWap project was begun in June 2000 as a joint venture between The Educational Centre for ICT in the University of Helsinki and the software company Fujitsu Invia. In this project a WAP-based project environment which utilized a shared database was developed In practice, this meant that if teachers came up with a good idea, they could immediately use a WAP phone to enter the idea in the database. This first Uniwap pilot was tested by 25 university teachers in connection with personnel training in 2001.

Based on the Uniwap -project the Educational Centre for ICT with its partners, Fujitsu Invia, Oy Radiolinja Ab, The Hypermedia laboratory at the University of Tampere and R5Vision, established "the Mobile Learning -project". The aim of this project is to develop the production of digital learning materials and construct models for teaching, studying and learning in mobile learning environments. The Uniwap environment has been improved, for example, the addition of SMS services and the transfer of digital pictures to the environment. These additions have now been tested in two pilots in the University of Helsinki. The first pilot was carried out on trainee teachers in the Department of Home Economics and Craft Science and the second one on students in the Department of Forest Resource Management. These two educational fields were chosen mainly because of two reasons. First, in both cases there was an instant need to diversify the way in which teaching was organised and to experiment with alternative pedagogical approaches. Second, in both disciplines there were personnel who had participated in the mobile pioneer group for personnel training. Both these groups of teachers were both skilled and eager to try to benefit from mobility in their own fields.

At the end of both projects, there was a group interview in which both the teachers and students participated. One of the researchers took notes during the interviews. It was also taped and transcribed. In the case of the forest students, a questionnaire, based on the issues that emerged in the interview was also completed by the students.

Mobility

We will start by defining the word "mobility" from the educational point of view. Kynäslahti (Kynäslahti 2002) claims that mobility has the following three elements:

1. convenience
2. expediency
3. immediacy

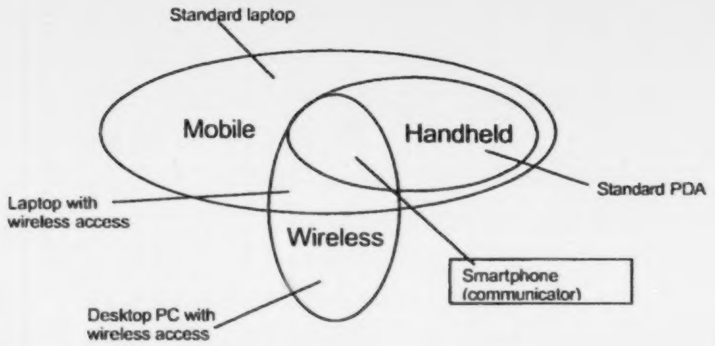
Kynäslahti arrived at these elements by asking the following questions which deal with mobility of teaching and learning.

Who/what is mobile?
Why is that person mobile?
Who is on the move?
Why is that person is on the move?

When we think of the question, who/what is mobile, we can obtain at least four different outcomes: 1) a teacher, 2) a learner, 3) some external specialist, 4) content (learning content, an animal etc.)

When we think of question why someone is mobile or on the move while he is teaching or learning, we can obtain the following answers: 1) The reason for moving is irrelevant to learning and teaching. The person happens to be moving while conducting educational activities. It has to do with convenience, rational time management etc. 2) Secondly the person just are on the move in some particular place or in places which are relevant regarding the subject that is being studied. This would be called the perspective of expediency. 3) The third essential aspect of mobility is immediacy. Users are able to perform an educational act immediately, even if it requires access to the Internet or a connection to other kinds of electronic environments, regardless of where they are. (Kynäslahti et al. 2002)

The word mobility can be defined also from a technical point of view. What devices which can used while we are learning in mobile situations?



Standard laptop
Mobile
Handheld
Standard PDA
Laptop with wireless access
Wireless
Smartphone (communicator)
Desktop PC with wireless access

Figure 1: Defining the mobile device (adapted from Siilasmaa 2002).

This figure defines the requirements for the mobile device which was to be used in this pilot project. First of all we can think of its mobile features. The traditional example of a mobile device is a standard laptop computer. It is portable and can be taken to many places. By adding the hand held feature to the mobile feature we can get a standard PDA (personal digital assistant) device. These devices (laptops and PDAs) do not yet offer the capabilities required to carry out tasks which were needed in this project. We also needed wireless access to a network. A wirelessly connected device can also be a desktop computer which is connected to a wireless local area network. By adding the mobile feature to the wireless feature we can obtain a laptop computer with WLAN access. But in this pilot we needed a device which is mobile, hand held and has wireless access to a network.

The device which meets all these requirements is a smartphone (Nokia Communicator 9210). In this project it was also important that the device has a www-browser. The browser enabled the user to upload digital pictures to appropriate locations in the learning materials.

Technical implementation

We set up a mobile learning environment for testing and evaluating purposes. We needed a device which can use existing wireless phone networks and is capable of data transfer and presentation. We also wanted to use a device which has features found both in PDAs and cellular phones. We came up with the Nokia 9210 Communicator because of its full feature keyboard and midsize colour screen. This device can handle common HTML-pages, WAP-pages, email and naturally SMS-messages. All of these techniques were to be used in this project. The learning materials were located in a web-based environment, and it was possible to have multichannel access to this environment. The database was accessible by PC www-browsers, smartphone www-browsers and wap-browsers. We also tested the transfer of digital pictures. We used infrared connections to transfer the pictures from digital cameras to the phone. We had to use quite a barebones user interface version of the phone so we could simultaneously transfer pictures and text material to the server. We could thus operate within the bandwidth limitations of GSM-networks. The figure below illustrates the technical implementation of the pilot project.

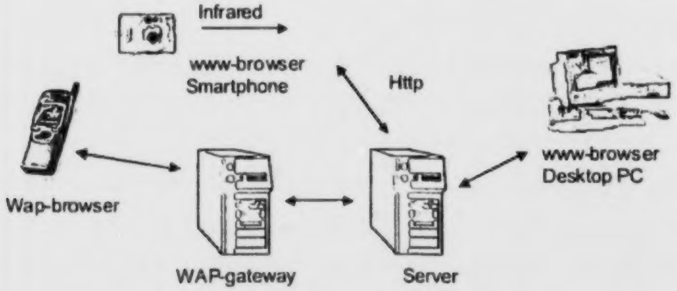


Figure 2. Technical implementation of the pilot project

Case: Mobile learning in teacher education at the Department of Home Economics

In spring 2002 we started the Uniwap -pilot for trainee teachers at the Department of Home Economics and Craft Science. There were eleven students and five teachers in this "mobile pilot". The Educational Centre for ICT lent the teachers and students 10 Nokia Communicator 9210s and two digital cameras (Casio QV-3000EX/Ir). We will take a closer look at this case in this section

Teacher education and mobility in teacher training

In Finland, prospective teachers are educated in departments of teacher education or other similar university departments. Successful trainee teachers obtain a Master of Education degree. The course work for the degree requires 160 study credits. One credit is equivalent to 40 hours of study. The teachers' pedagogical studies include educational studies, didactics and teacher training. The purpose of teacher training is to train students to plan and organize their teaching duties. For many students, the teacher training course is their first practical contact with the everyday life of a teacher. Students have the opportunity to use their own knowledge, experiences and personal characteristics and grow into a capable teacher. The development of a professional identity and skills are supported by supervising teacher.

In this case we used the virtual teacher training instruction model (Tuononen & Kurola 2002). This means that the students are instructed in three different ways: 1) face-to-face instruction, 2) instruction via a network based learning environment and 3) instruction via a mobile device. Face-to-face instruction is the traditional method where student and supervisor discuss practice teaching sessions. Network-based-instruction means that supervisor uses a learning management system to interact with the students. The supervisor can deliver training material by various methods including the Internet. The third method is the use of mobile devices for instruction. The main idea of the virtual teacher training instruction model is that the student has the possibility to document all aspects of his/her teacher training. Face-to-face instruction is nowadays more or less the prescriptive way to instruct trainees. The trainee always has the opportunity to ask questions and to go back to the network based or mobile instruction documents for more details. The supervisor can for example use a mobile device to have real time conference calls with his/her students. When this is done the supervisor is able to reach all his/her students even if they are physically in different places. There are many other examples of how a supervisor can support the instruction of trainees using mobile devices.

How the pilot was carried out

The mean aim of pilot was to enable teacher and students to discuss teaching methods, through mobile devices and also to use SMS-messages and digital pictures as a part of the course. The pilot also enabled supervisors to take digital pictures of various teacher training occasions, the learners' throughput and different teaching techniques. The trainees themselves could also make their wishes concerning what pictures the supervisor should take. The pictures could be downloaded from the phone to the camera via an infrared connection. The pictures could then be uploaded using a www-browser to the trainee's material bank in a Uniwap-database even before the training session had finished. Moreover, the supervisor may write down ideas and feedback related to the training session and send them to the trainees. The trainees then put together a digital portfolio on the basis of the photographs and a network discussion.

Case: Mobile learning at the Department of Forest Resource Management

The other case study was made at the Department of Forest Resource Management. Fifteen students and three teachers took part in the pilot. This pilot was part of a course called "The forest planning and inventory project". The participants used the same equipment as the students of home economics. So, the technical infrastructure and other functions were exactly as those used in the home economic pilot. The use context was different, as the users used their mobile devices for different purposes.

Studying at the Department of Forest Resource Management

Forest Mensuration and Management is an applied science that relies on informatics, forest economics and biological sciences as applied to forests. This subject helps the student to obtain the knowledge and skills needed for measuring the qualitative and quantitative characteristics of trees, forest stands and any larger forest area. Students majoring in this field learn to apply remote sensing, statistical sampling techniques and GIS to forest inventory and monitoring and they obtain knowledge essential for building and applying models that describe the development and states of forests. The management planning of forests resources with multiple objectives is an important part of this field. The teaching is based on lectures with exercises, field courses, problem-based learning, the literature of the field and seminars. (Student's Guide 2002)

How the pilot was carried out

The substantial themes of the course were acquisition of spatial data (geoinformatics) and planning methods, especially multi-criteria decision analysis. The stimulated situation for the student groups was to act as advisers for landscape planning for the Viikki campus area. The students were divided into two groups. One group worked in the forests and the other group of students, the analyzing group, were in the classroom . To complete the task, the forest group, needed to walk all over the campus, choose different kinds of scenery, take digital photographs and determine the GPS-coordinates of the corresponding points. After the pictures and metadata had been wirelessly transferred to the database using mobile devices, the analysis phase took place in the computer classroom. GIS-software was utilised in order to place the GPS-points on the map. Furthermore, web-based decision support software was used to complete the scenery comparison.

Results

We looked at the three different elements for mobility (according to Kynäslahti) and compared them to the feedback, which we collected from the students and teachers. The elements were convenience, expediency and immediacy.

First we examined aspects of convenience The students felt that the reason they were mobile was that they wanted to use their idle moments for educational activities. For example, they, wrote notes or memos to be shared with other students on the bus or train. They uploaded pictures from their phones to the material bank. All of these examples deal with convenience. The university students had the opportunity to use their time rationally even when they were on the move.

The second element is expediency. The students moved between various locations. Trainee teachers worked in a classroom environment and they also conducted activities in many other places while they were on the move. From the expediency point of view teacher trainees pointed out that they had to work at home and they did not have any other access to the Internet apart from their phones. Trainees also mentioned that they used the phones in stores when they had to check if there were particular foodstuff at school which they needed in their trainee home economics lessons. In these cases they mostly used audio calls and SMS-messaging. The trainees wanted to move pictures from the camera to the phone right away and most of the time this was possible in the classroom. They felt that without mobility the working method with the camera would not have been appropriate. The forest management students also had to send pictures and coordinates right away to the analyzing group.

The third element is immediacy. This element was most meaningful for the trainee teachers. They liked the fact that they were able to act immediately. They wrote memos and took pictures while they were observing other trainees' lessons. The trainees had an immediate need to write down their thoughts and ideas to be shared with other trainees. One trainee said that she got a great idea on the way to university very early in the morning and was happy to be able to share this idea with other class members right away. A mobile device is a great tool for giving feedback at the same time as observing other trainees. We found that there was a difference in the way feedback was given between supervisors and trainees. Trainees gave immediate feedback to other trainees while they were observing. They acted spontaneously. The supervisors were more careful and did not give spontaneous feedback, they thought more deeply about what to write. For example they read through their message text before they sent it and corrected any typos that might be present, while the trainees typed the text and send it without checking.

Forest management students thought that from the immediacy point of view the idea that the user could send pictures and coordinates immediately was great. They often had to make long trips to the forests and they had to be able to share information and material with analyzers or with their supervisors in working life. However, some students criticised the way the course was assessed. The main reason for these criticisms was possibly a failure to appreciate the immediacy aspect of mobility. Some of the students remarked sarcastically that the process of transferring pictures from a digital camera to the Communicator and, their counterparts in the computer room took so much time that it would have been easier to walk to the room and transmit the information directly to PC. This can be seen as a severe disadvantage of the project. However, the immediacy aspect was important for the teachers who guided the process and for students as well when they needed instant help.

The teachers' opinions about mobility and the use of mobile devices were also mostly positive. During teacher training supervising teachers need to work long hours and for that reason they felt that the use of mobile devices helped their work a lot. Teachers need to go from one school to another many times during the day, and while they were travelling they were able to connect to the shared database. Also, teachers felt that mobile devices brought more flexibility to their time usage planning.

The massive use of Uniwap was surprising. During these two pilots there were all together 528 SMS-messages or digital pictures in the Uniwap database. The students of home economics were more active than students of forest resource, they sent a total of 388 messages while the students of forest resource sent 144 messages.

The reason for this difference could be the observation that the trainee teachers used the mobile device and Uniwap as a photo gallery of funny pictures which they had taken during classes. The students of forest resource used the Uniwap strictly for their studies.

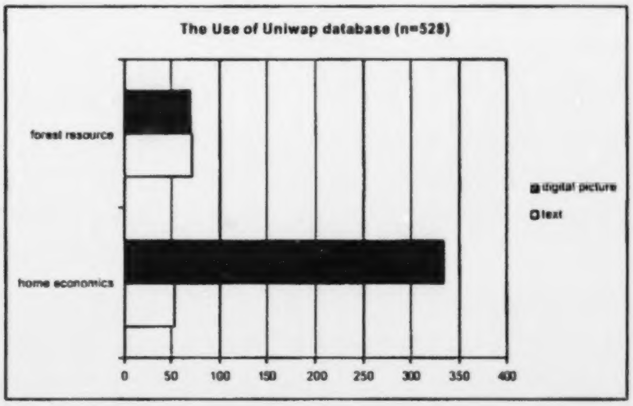

Figure 3. The number of messages and digital pictures in the Uniwap-database.

There were some differences in Uniwap usage times between these two pilots. In the home economics pilot the use of Uniwap was most active at the end of the working week, because most of the trainee lessons were held then. Uniwap was actively used almost round the clock, messages were sent by SMS between 9.39 am and midnight to 12.11 am. The supervising teachers especially sent SMS-messages quite late at night. The main reason for using SMS-messaging was give students feedback after a supervisor had read a trainee student's plan for a lesson. This component of the supervisors' work usually took place at home late in the evening. One supervising teacher said that when she have the possibility to get in touch with her students by using a mobile device and the Uniwap database at any time of the day, it helped her supervising process.

The teachers in the forest resource pilot mainly had the same opinion about freedom to contact students around the clock, but they didn't use that possibility so much. Most messages in this second pilot were sent between 8 am and 6 pm.

When analysing the contents of SMSmessages, we found three kind of situations, in which SMS was used: giving information, supervising and feedback. Mostly SMS-messages were used to send general information. Teachers sent information about the next class meetings or notified students that their feedbacks or assessments were now available. Also students notified other students and teachers of their plans or GPS-coordinates with digital pictures were ready and if they needed feedback.

The most interesting aspect of these pilots was however the number of digital pictures which were taken and uploaded to the Uniwap-database (see Figure 3), especially in the home economics pilot. The reasons for this huge number of digital pictures were that teachers and students found the possibility so much fun that they wanted to take many pictures of every trainee lesson and situation. Because you could upload the picture and notes right away to the database, everybody was able to comment and give feedback instantly. This immediacy, the third element of mobility, was very important and without this "right-away -possibility" the transfer of digital pictures would not have been used so much.

Students thought that the digital pictures helped to grow their professional identity as teachers of home economics. They saw, in so cases for the first time, how they looked in front of an elementary school class and how they taught them. The use of still-pictures helped students and supervisors to see things that they did not notice in the actual situations. This was very helpful in discussions between the students and their supervisors when the students analyzed their own teaching methods and made notes in their portfolios.

Koskinen (Koskinen et al. 2001) points out in their research that digital pictures without text are not interesting. With text you can clarify the situation in picture, why it was important to take or what happened afterwards. In our pilot the text was added to digital pictures during or after they had been uploaded to the Uniwap-database. The students changed the titles of the pictures and wrote little messages describing what was happening in the pictures. Supervising teachers expanded the picture message by giving feedback or asking questions about the situations in the classroom. This way the digital pictures came alive also to people who were not present in the actual teaching situations, such as other trainee students and researchers.

Conclusion

The project brought together Finnish mobile learning innovators in a networked organization. On the national level it made a great contribution to the development and research into mobility in educational use.
Both mobile pilots, i.e., at the Department of Home Economics and Craft Science and ate Department of Forest Resource Management showed that the educational use of mobile device and pedagogical opportunities of mobile learning are worth further research and testing. The Educational Centre for ICT continues to use education and testing pilots to spread these innovative methods to other units at the University of Helsinki and possibly to the Finnish Virtual University. The long-term goal is to create flexible teaching solutions, which will enable access to information with all kinds of devices, and to produce materials flexibly in a variety of situations.

Mobile technology is only beginning to take its first steps in academic teaching and studying. The opportunities it creates have been recognised and the idea of a wireless campus is spreading to universities. The integration of the Internet and mobile solutions will transform the use of ICT in teaching and take it in the direction of open teaching, provided that mobile technology is seen as a candidate for the development of academic teaching and education. The core characteristic of mobile learning is that it enables learners to be in the right place at the right time, that is, to be where they are able to experience the authentic joy of learning.

The mission of Radiolinja is to create and facilitate a wireless lifestyle – a Mobile Society. The role of the Technology Center of Radiolinja is to participate in innovative research and development projects. The main aim of those projects is to explore future wireless lifestyles. Radiolinja sees the support of learning and teaching with mobile devices as one of its future possibilities. By taking part in, and supporting these innovative research studies Radiolinja can be certain that it is also promoting the direction that wireless lifestyles will take in the future.

Instructional Models and Scenarios for an Open Learning Repository - Instructional Design and Metadata

Heidrun Allert, Hadhami Dhraief, Tobias Kunze, Wolfgang Nejdl, Christoph Richter
{allert, richter, nejdl}@learninglab.de
{dhraief, kunze}@kbs.uni-hannover.de
Learning Lab Lower Saxony, University of Hanover, Germany

Abstract: We present and discuss the evolution of a metadata-based course portal, the Open Learning Repository. Different instructional models and learning principles are integrated in order to meet different learning and teaching strategies: different metadata models (domain model, instructional model, cooperative and structural model) are designed and mapped. A scenario-based evaluation of a former version of OLR revealed that the use which was intended by designers and teachers can differ from actual use by learners. In the current version we do not only implement different instructional principles and theories but also help-files which address the learners reflection of their own learning strategies. In the design process, different learning theories as well as the organizational framework serve as relevant context which is addressed by scenarios written by all stakeholders. Scenarios serve as medium for communication between instructional designers, computer scientists, and teaching staff.

Motivation

Our Open Learning Repositories (OLR for short) are metadata-based course portals, which structure and connect modularised course materials, which can be distributed all over the Web. The modular content is integrated by explicit metadata information in order to build courses and connected sets of learning materials. Modular content can be reused for other courses and in other contexts, leading to a course portal which integrates learning objects from different sources and authors. Semantic annotation is necessary for authors to help them choose Learning Objects and to connect them into course structures. We use a relational database to store all metadata. We don't store content in the database itself, but reference it by URLs. We are currently using the OLR system in the context of two courses, one in Artificial Intelligence and one in Software Engineering.

The focus in the first and second generation of our Open Learning Repositories (Dhraief et al., 2001) was the technical infrastructure. The main questions were, how to store the metadata, whether to use O-Telos (Mylopoulos et al., 1990), XML or RDF (World Wide Web Consortium, 1999) etc. We also implemented different navigation interfaces. Different views on a given course are offered to students, realized by different queries and page designs. A user has the choice between a hierarchical tree-like navigation, a trail navigation, where he can move forward and backward on a trail, and semantic (context) net navigation.

However, there was a lack of pedagogical background in the first and second generation of OLRs. Therefore we decided to design and implement a new generation of OLR, which we call OLR3. In a team of computer scientists and educational researchers we focused explicitly on the goal to use such an open learning repository to enhance teaching and learning. We have implemented different instructional models and extended the Learning Object Metadata Standard LOM (IEEE Learning Technology Standards Committee, 2002) to incorporate our strong focus on educational theories. Also, as the results of the evaluation of the second generation of the Open Learning Repository revealed that the system did not meet the students needs, we addressed the entire educational setting which is supported by technology instead of focussing on the technology in an isolated way. For this, we developed a scenario-based approach to guide the design process of OLR3 in order to address both the technology as well as the educational setting, which influences the use of an e-Learning system. The multi-disciplinarity of the project team required a medium for communication that allows to communicate ideas and theories beyond the different areas of expertise. The scenario-based approach helped to handle this task.

The Open Learning Repository (OLR3): Technological Aspects

In this chapter, we will give an overview on the architecture of the 3rd generation of OLR, its current functionalities, and its web interface.

Architecture and Technology

The 3rd generation of our Open Learning Repository, OLR3, is implemented in Java and works as a JavaServlet, running on an Enhydra (Madl et al., 2002) Application Server (which has been developed as open source). It is connected to an Oracle Database via JDBC, which is used to store the metadata entered by course authors and students. There are two types of metadata: structure-metadata and annotation-metadata. The structure metadata represent information about the structure of a given course or course unit, the navigation path within this course or course unit and the relations between different learning objects. Annotation metadata represent the information about the content itself. We are using (a subset of) the LOM metadata standard to annotate the learning objects. All metadata are represented in RDF and RDFS (World Wide Web Consortium, 2002). The RDF schemes, needed for either the annotation or the structure of learning, can resided anywhere on the Web, as do the learning objects. The database does only hold the metadata, and assembles the course from these data., which

The system works on a "StatementPool",which holds all metadata known to the system at runtime, relevant for a given course. When an author starts working on a course, the pool is filled with the already existing data about that course from the database, and all statements from the used RDF schemes. Any referenced RDF schema will be parsed using the SiRPAC RDF parser (Melnik, 2001), whereas imported RDF files are parsed by a VRP RDF parser (Tolle, 2001), which provides semantical checks against given RDF schema rules.

Figure 1: OLR Architecture

Web Interface

OLR3 provides a web-browser based metadata editor/viewer and two major user interfaces: The first one is used for readers preferring a more graphically oriented view and only minor functions for manipulation of the underlying metadata. The second one is designed for authors to provide a schema-driven and browser-based metadata editor with flexible binding to different RDF schemes.

BEST COPY AVAILABL

Learner Web Interface

Learners of a given course can navigate through an existing course structure, displayed as a tree and extended by additional, metadata-defined images for better understanding. As we will see in the second part of this paper we implemented two instructional models in our OLR3 prototype for the course "Introduction to Artificial Intelligence". Within that tree the user may select course elements, whose content will be displayed in the center of the screen. A specific engine prepares and filters the content, and displays it based on a stored layout. The reader interface also offers the reader the possibility of making minor additions to the metadata of a selected course element by providing functions like "add comment", "add bookmark", "add keyword to metadata" etc. All those additions can be made private or public to other course readers.

Author Web Interface

The second interface provides the actual metadata editor which is intended for course authors, who can navigate through the structure tree of a course and select any sub-element. All existing editable metadata for this element are shown in the center of the screen, and the user can choose from a set of existing RDF properties, to add to the metadata, or to modify the existing data. The author can also bind RDF schemes (e.g. DC, DCQ, LOM) stored on the Web to extend the set of available properties for annotation, or unbind RDF schemes, that are not needed anymore. A "toolbar" holds those bound RDF schemes and offers the possibility of navigating through their structure by displaying an expandable tree view of any available property.

Different Views on Learning Material: Three Models

Learning management systems and learning environments as well as standards for metadata in the field of learning often implement or address only specific learning and teaching principles, theories and models. These learning theories are addressed either implicitly or (sometimes) explicitly. This means that neither teachers nor learners can choose a way of learning suited best to their preferred learning strategy or learning style. In a life long learning context, however, learners have to be able to decide on learning needs themselves and should be able to choose a preferred way of learning themselves. This requires reflection on ones own strategies of learning and teaching. Rautenstrauch (2001) explains: *Life-long learning will be a learners own decision (...) the learner is mature (...) he will identify and define his own needs and prefered ways of learning (...) he will learn to learn self-organized, self-determined, and independent from predetermined curricula and institutional forms of organization.*

We therefore designed the Open Learning Repository (OLR3) open to different learning and teaching strategies. In order to be able to implement diverse learning models we separated different metadata-models: the *Domain Model* and the *Instructional Model*. Furthermore, we offer different navigational structures: guiding sequences (supporting learning processes) as well as links to related learning objects (supporting exploration and elaboration), in order to face the different needs of novices and experts. We implemented two different learning models which can be assigned to different paradigms/epistemologies: a learning sequence designed along Ausubel's theory of Expository Teaching (Ausubel, 1968), which is assigned to cognitivistic theory, and a PBL model (Problem-Based Learning) (Wiesenfarth, 1992) which is associated with situated approaches.

Modeling different spaces or metadata-models in OLR is a means of representing different views on learning material. In the OLR we have three main spaces to model different aspects/views: *Domain Model*, *Instructional Model*, *Structural and Cooperative Model*. These different models can be structured by different experts in the different fields (experts in the subject domain may structure the *Domain Model* whereas instructional designers may extend the *Instructional Model*)

Domain Model

In the *Domain Model* domain and subject specific ontologies are specified, mainly including MatterOfFactRelations, both hierarchical and associative (cp. Meder, 2000). This knowledge space includes structuring of subject specific knowledge, subject specific skills and competencies.

Instructional Model

There is no unique instructional ontology but different approaches, theories and models. In the Instructional Model instructional phases and relations are specified. They are derived from different instructional models and learning theories. Furthermore learning processes are modelled along different instructional principles (PBL, Case-based etc.). Trying to represent these aspects in learning object metadata, we realized that existing metadata standards do not address learning processes (Allert et al., 2002), an issue also discussed by Meder, who stresses, that learning objects should be defined in six dimensions (Meder, 2000), where one of these dimensions defines the position of an learning object within the process of knowledge acquisition: *A learning object must be defined in the dimension of logic-operative modes of processes, i.e. there are methods which determine the process of acquisition of knowledge. („Ein didaktisches Objekt muss bestimmt sein (...) in der Dimension logisch-operativer Verlaufsformen, d.h. es gibt Methoden – im definierten Sinne – die den Verlauf der Aneignung von Wissen bestimmen können")* (Meder, 2000)

Up to now we implemented two different instructional models derived from different principles and paradigms: Expository Teaching by Ausubel (cognistivism) and a Problem-based model (situated approach) (see Tab. 1).

Phases we modelled along the Expository Teaching by Ausubel (1968):	Phases we modelled along the PBL model of Wiesenfarth (1992):
Phases	**Phases**
Advance Organizer (orientation)	Set Goal
Progressive Differentiation (conceptualization)	Specify Criteria
Practice	Acquire Knowledge
Integrating and Connecting	Generate Ideas
Relations between them are „followed by".	Realize Implementation
	Reflect
	Generalize

Table 1: Phases modelled in OLR3

These different guiding structures (learning processes and phases), specified in the *Instructional Model*, serve as threads and address the problem of linking decontextualized objects to stringent learning sequences and coherent structures. We defined instructional roles of learning objects within each phase. The Expository model as well as the PBL model work as guidance to authors presenting learning material as well as to students navigating through the material. The PBL model also guides students structuring their own project work. The phases which are modeled in the *Instructional Model* represent the structure at the interface. The learner can choose from two views on the learning material: "learning sequence" (Expository model) and "problem solving path" (PBL model).

Structural and Cooperative Model

Whereas in the *Instructional Model* learning models and processes are specified in order to support guidance, in the *Structural and Cooperative Model* relations are specified in order to support exploration and elaboration. Course authors may use the Relations to integrate further material and learning objects, beyond the thread of guidance. There are different kinds of relations:

- Methodical and Structural Relations
- Cooperation-Supporting Relations
- Learner Activities.

Examples for methodical and structural relations are:

- Theory generalizes example.

- Exercise applies theory.

Entity	Relation	Entity
theory	generalizes	example
exercise	applies	theory
...		

Table 1: Methodical Relations specified in the *Structural and Cooperative Model*, expressed as Triple

In order to model these relations, each learning object must be categorized methodically. In this *Structural and Cooperative Model* learner activities are modelled, too. Examples for learner activities are:

- Add keyword to metadata
- Add relation
- Add comment

Cooperative relations are modelled to guide students cooperative work. Next to the "problem solving path" relations are offered which motivate students to compare the progression of their project with others' or to compare the organization and coordination of projects within teams. These relations are planned to be implemented in the OLR3.

Based on these models the new interface of the OLR3 will look as shown in Fig. 2. This new interface is based on results of the scenario-based-evaluation of the former version of OLR (OLR2).

Scenario-Based Evaluation and Design

In this section different aspects of the scenario-based evaluation and design of the OLR will be highlighted. First the evaluation of the previous version of the OLR is briefly described. Then the impact of organizational and educational context for the design of a computer supported learning environment like the OLR3 is discussed. Furthermore the relevance of scenarios as a medium for communication will be stressed.

Evaluation of a Former Version of the OLR

The scenario-based[1] evaluation of the previous version of the OLR has been an important starting point for the design of our current version. In an evaluation survey 20 students, which had attended an introductory

---

[1] We use the term scenario to refer to a narrative description of a situation of use. (Carroll, 2000) states that a scenario is characterized by a setting, includes agents and actors with individual goals or objectives and describes in contrast to

BEST COPY AVAILABLE

course on Artificial Intelligence, participated in semi-structured interviews. The lecture notes of this course on Artificial Intelligence had been provided to the students via the OLR. The aim of this survey was to explore how the OLR could be improved. On the basis of these interviews a scenario-of-actual-use was written. In addition the designers, teachers, and developers of the OLR were asked to write scenarios-of-intended-use in order to express their ideas of how the OLR should be used by the students. The comparison of the scenario-of-actual-use and the scenarios-of-intended-use revealed that the OLR had been used in a very restricted way by the students. Much of the functionality implemented in the OLR had not been used, or had been judged as not useful/necessary for reaching the course objectives. The survey is described in more detail in a technical report (Richter & Allert, 2002).

We are convinced that the mismatch between the use made by the students and the functionality implemented in the OLR can be assigned at least partly to the characteristics of the educational context in which the OLR was embedded. The students concentrated on objectives determined by the course and its embedding in the organizational structure (the course was held in a rather conventional way). These objectives contradicted main ideas underlying the design of the OLR. For example, while the OLR tries to provide a broad range of diverse material on a topic, this feature was at least unnecessary or sometimes even counterproductive to prepare for the exams which focused on the core material. As a consequence (besides changing the course structure and focus in the next semester) we suggest not only to implement different learning principles and modules but also help-files, which address the learners' reflection of learning strategies, acknowledging the fact that choosing from different learn ing modules requires reflection on ones own activities of learning. We are going to create the help-files on the basis of scenarios that describe the different underlying educational ideas on the level of concrete human activities.

The Meaning of Contextual Conditions for the Design of the OLR3

The evaluation revealed that it is crucial to address the educational context as well as characteristics of the learners more carefully in the design of the OLR3. The most important aspect of the educational context that influences the use of learning materiasl are the (often implicit) learning objectives. While in many educational settings some learning objectives as the acquisition of domain specific knowledge are named explicitly, other possible learning objectives stay more or less implicit., for example the acquisition of social competencies.

A precise description of implicit and explicit learning objectives within a given educational setting and their possible impact on students activities are therefore very important to make comprehensible design decisions. Only if conflicts between the learning objectives within a given educational setting and the learning objectives of the eLearning system are anticipated, it will be possible to decide if the system should be adapted to the educational setting or vice versa. This problem will be even more important if the learning system is constructed on a special educational model with explicit learning objectives and a certain conception of the learner. We assume that focussed changes in learning can only be fruitful in interaction with organizational changes (lecture and exams etc.) – nothing will not change if we simply offer a new e-Learning system to the students. The use of a learning environment such as the OLR3 has therefore to be understood as a part of more complex and longer lasting students' learning activity.

The educational setting with its implicit and explicit learning objectives and their possible impacts on students activities will constitute the context, which is addressed by scenarios written by all stakeholders. Scenarios of use appear to be an adequate way to describe the possible impacts of the context, because they force the writer to think about the specific behaviour of the user.

Scenarios as a Medium for Communication

Beside the fact that scenarios seem to be an adequate way of describing the use of a certain artefact on different levels of abstraction and can serve to highlight different perspectives on one task they additionally serve as a medium for communication between all involved stakeholders. A collective base for communication is of great importance because of the multidisciplinary design team involved in the design of the OLR3, consisting of instructional designers, computer scientists and teachers. In the development of any kind of educational material many different variables like the learning content, the underlying instructional models, characteristics of

---

conventional Use-Cases more complex sequences of human action. We apply situations of use in a very broad sense., for example, attending a lecture by a student is a situation of use.

the learner, characteristics of the educational context, and technological requirements have to be taken into consideration (cp. Tergan, 2000). It is unrealistic to recommend that every stakeholder has expertise in all the addressed topics. While the cooperation of a multidisciplinary design team allows to address many relevant topics it is still necessary (and sometimes even more important) to find ways to communicate the different ideas, concerns etc. within the design team. Scenarios seem to provide such a collective base for communication within the project. The necessity to formulate the possible consequences of certain variables, theories etc. on the concrete behaviour of an actor can assure the necessary information to make informed design decisions, and allows them to be communicated to the whole team. An adequate medium for communication is also an important condition to understand already made design decisions and as a starting point for further evaluation procedures.

Further Work

We are currently extending OLR functionality by a new user-interface as mentioned before. On the one hand the design of the new user-interface as well as the help files will be based on the results of the evaluation of the second generation of OLR. On the other hand the design will be guided by new scenarios-of-use that will address pedagogical theories and general conditions of the educational setting explicitly. We will also change the educational setting in which the OLR3 will be used in the next year to support a broader use of the OLR3 and the embedded learning materials. Good structured learning materials are very important for conventional learning and teaching, but appropriate and well structured learning materials for e-learning are absolutely crucial.

Cognitive Styles and Medical Students' Learning

AlRawahi, Z.
Sultan Qaboos University
Sultanate of Oman
E-mail: rawahiz@squ.edu.om

Abstract: Whilst a number of systems have been developed based on cognitive styles, and a significant body of research has been carried about learning with multiple representations, little was known about the effectiveness of systems based on multiple intelligences (MI). To address this, a prototype was built based on Gardner's theory of multiple intelligences and experiments were performed to study the effectiveness of the system on medical students' learning. The results showed that medical students accomplish deeper understanding of a topic when it is taught in a way that matches their cognitive styles. Moreover, the results indicated that providing students with a rich environment in which they can learn a topic via their chosen modality seems not to be as an effective teaching method as automatically adapting the material.

Introduction

The Interactive Medical Library (IML) prototype is a multimedia library in Medicine that adapts to learners' cognitive styles (AlRawahi, 1999). The IML act as a database which contains a large amount of information such as medical images, digital videos, textual information, laboratory data, etc. The Interactive Medical Library attempts to be a source of information that learners can return to whenever they need to confirm their understanding or to review and study certain medical material.

The design of the IML prototype was influenced by Gardner theory of Multiple Intelligences. In his multiple intelligences (MI) theory Gardner in 1983 claims that every cultural role requires a combination of different abilities regardless of the sophistication. He considers a person's mind as a collection of more than one intelligence or ability. He categorized the following kinds of intelligence: Linguistic, Logical-Mathematical, Spatial, Musical, Bodily-Kinesthetic, Interpersonal, Intrapersonal and Natural. They work together depending on the problem to be solved, within the limitations imposed by the individual environment. Some activities require the higher progress of a single intelligence, while others require development in more than one practice (Gardner, 1993a). According to Gardner "Nearly all cultural roles exploit more than one intelligence; at the same time, no performance can come about simply through the exercise of a single intelligence."(Gardner, 1993b p.27)

Thus, the aim of this paper is to examine the effectiveness of a multimedia system (Interactive Medical Library prototype) that supports cognitive styles based on the theory of Multiple Intelligences in medical students' learning.

Method

Subjects

The subjects were 44 medical students in their fifth year of medical training from the Sultan Qaboos University (Oman). The subjects were randomly divided into four study groups according to the learning environment that they were given in the hypermedia library of the Hospital Round prototype.

Procedure

The medical students were divided into four study groups. These groups were a Cognitive Style group, an Opposite to Cognitive Style group, a Traditional group and a Modality group. The Cognitive Style group was given material to study in keeping with their learning styles. The opposite to Cognitive Style group was given material to study opposite to their learning styles. The Traditional group was given material in various representations according to the method used in traditional teaching. Finally, the Multiple Representation or the Modality group could choose the modality they wished to learn with from a number of representations.

All subjects were given the Multiple Intelligences Developmental Assessment Scale (Shearer, 1996) questionnaire to fill out and they were asked to return the questionnaire and to come for the rest of the experiment on the following day. On the experiment day, the subjects were initially given the United States Medical Licensing Examination (USMLE) - step 1 to solve as a pre-test. After solving the pre-test questions each subject was given a demonstration about how to work with the computer using the Virtual Hospital Round Prototype. The subjects were then asked to work with a clinical case in the Cyber-Round individually. The cases in the Cyber-Round varied, some cases were relevant to the material in the library and other cases were not relevant to the material in the library. After working with a case, the subjects had to read 1-2 pages of medical material from the hypermedia library. Furthermore, according to the group the material that was given was:

a) according to their cognitive styles,
b) opposite of their cognitive styles,
c) according to the traditional way of teaching the topic, or
d) by using modality choices.

Soon afterwards, the subjects were given another clinical case to solve. Lastly, the subjects were given the USMLE post-test. The experimental structure is in Appendix I.

Hypotheses

The hypothesis was that students who were to be given material that adapted to their cognitive styles would do much better in understanding the medical material than all the other groups. In contrast, students who were to be given material opposite to their cognitive style their performance would do worse than all the other groups. While students who were to be assigned to a multiple modality group would outperform the students in the traditional group.

Testing Students' Medical Knowledge

The United States Medical Licensing Examination (USMLE) was used to test medical students' medical knowledge. This test is one of the standardised types of test normally used by various medical schools and testing authorities to test medical students and clinicians. The USMLE comes in three versions: Step 1, for medical knowledge, applicable for testing undergraduate medical students; Step 2, for resident and graduate students, who have just finished their clinical training; Lastly, Step 3 for clinicians who have some years of work experience. We used the Exam Master software product of the Exam Master Corporation to administer this test to our subjects. The Exam Master software allows the user to select certain topics to be examined in.

Since, our IML prototype focuses on Cardiovascular diseases, we selected for the test the subject of cardiovascular diseases and mainly the diseases of blood vessels and heart. This test contains 15 multiple choices questions. All subjects were given the same medical knowledge test twice, as a pre-test and then as a post-test. The first test was before working with the IML prototype and the second test was when they had finished working on all the activities of the prototype. The order of questions in the test was different in the pre-test and post-test. The function of these tests is to give us an idea about students' medical knowledge prior and after working with the Virtual Hospital Round Prototype. This test is described in Appendix II.

Structuring the learning representation

This section discusses the type of intelligences comprised in each group and the corresponding representations in the IML. The construction of different intelligence profiles in the IML involves a blend of various intelligences. These combinations are:

Profile 1: Visual > Linguistic > Musical;
Profile 2: Linguistic > Visual > Musical;
Profile 3: Linguistic > Musical > Visual,
Profile 4: Visual > Musical > Linguistic.

The profile (Visual > Linguistic > Musical) means that a student has a high visual, medium linguistic and low musical intelligence. Some students exhibited a slightly different profile such as *Visual = Linguistic > Musical; Visual > Linguistic = Musical; or Musical = Linguistic > Visual*. In order to verify the type of students' intelligences we used students' study habits and preferences as a second measure. Medical students' study preferences were gathered - by asking students about what do they think their preferences are - to verify weather the MIDAS profile matched the students' study preferences. These were included in the previous combination.

As mentioned earlier the Cognitive Style group were given representations that adapted to their intelligence profile, whilst the Opposite to the Cognitive Style group were given representations opposite to their intelligence profile. MIDAS profiles and the representations given in the hypermedia library of the IML are shown in Table 1 below. All the students in the Traditional group were given a mixed type of representation similar to the one used in conventional teaching. All the students in the Modality group were given multiple representations to choose from. The students in this group selected a representation according to their preferences.

	Multiple Intelligences Profile	Representation given in the IML
CS	*I. Visual > linguistic > musical*	*I. Visual > linguistic > musical*
	II. Linguistic > visual > musical	*II. Linguistic > visual > musical*
	III. Linguistic > musical > visual	*III. Linguistic > musical > visual*
	IV. Visual > musical > linguistic	*IV. Visual > musical > linguistic*
OCS	*I. Visual > linguistic > musical*	*III. Linguistic > musical > visual*
	II. Linguistic > visual > musical	*IV. Visual > musical > linguistic*
	III. Linguistic > musical > visual	*I. Visual > linguistic > musical*
	IV. Visual > musical > linguistic	*II. Linguistic > visual > musical*

Table 1. Categorization of the learning environment in the Cognitive Style group and the Opposite to the Cognitive Style group.

The numbers of subjects in the four groups were as follows:

CS	Cognitive Style Group(n=12)
OCS	Opposite to Cognitive Style Group(n=12)
TRAD	Traditional Group (n=10)
MR	Modality Group(n=10)

Results

Learning Modality and Individual Competence

The results of USMLE

The means and standard deviations of students' correct answer out of 15 questions in each learning environment are presented in Table 2 below.

	CS	OCS	TRAD	MR	Overall
Pre-Test	6.58 (1.56)	6.75 (1.71)	5.80 (2.15)	6.20 (1.75)	6.36 (1.77)
Post-Test	10.67 (2.06)	8.08 (1.31)	8.60 (1.78)	8.40 (1.90)	8.98 (2.02)

Table 2. Mean (standard deviation) of students' correct answers out of 15 questions in each learning environment.

	CS	OCS	TRAD	MR	Overall
Pre-Test	43.89 (10.43)	45 (11.41)	38.67 (14.33)	41.33 (11.67)	42.4 (11.8)
Post-Test	71.11 (13.73)	53.89 (8.74)	57.33 (11.84)	56 (12.65)	59.87 (13.47)

Table 3. Mean(standard deviation) of students' percentage of correct answers in each learning environment.

There was a gain from pre-test to post-test for each of the four learning environments. The mean gain for the cognitive style group was greater than all the other three groups (percentage gain is 27.22). In contrast, the mean gain for the opposite to the cognitive style group was worse than all the other three groups (percentage gain is 8.89). The percentage gain in the traditional group and in the modality group are 18.67 and 16.67 respectively. The graph below presents the USMLE pre-test and post-test results for the four learning environments.

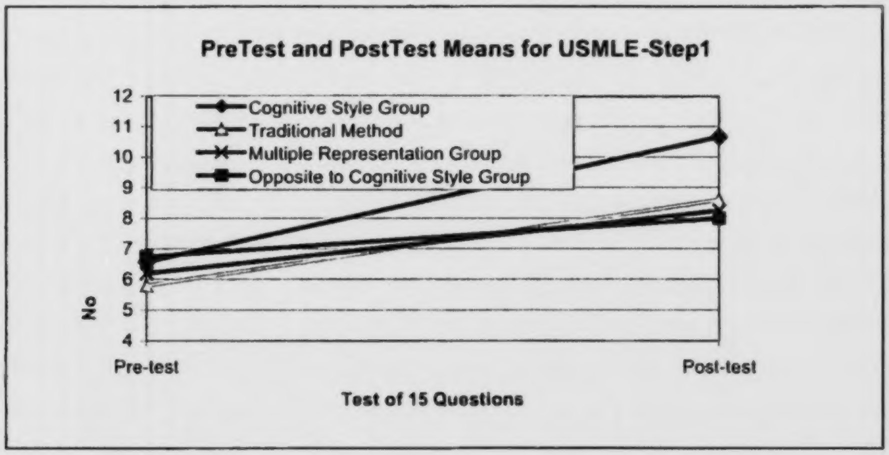

Figure 1. The result of USMLE pre/post tests in different learning environments.

BEST COPY AVAILABLE

A one way analysis of variance (ANOVA) was performed to see if there was any significant variation between the results of different learning environment groups in the pre-test and post-test. Table4 shows the between groups and the within groups differences.

ANOVA

		Sum of Squares	df	Mean Square	F	Sig.
PreTest	Between Groups	5.815	3	1.938	.604	.616
	Within Groups	128.367	40	3.209		
	Total	134.182	43			
PostTest	Between Groups	48.594	3	16.198	5.127	.004
	Within Groups	126.383	40	3.160		
	Total	174.977	43			

Table 4. ANOVA results of the pre-test and the post-test

The results of the ANOVA shows that there was a significant difference between different groups in the post-test F (3,40) =5.127; P = 0.004, and no significant differences between groups in the pre-test F (3,40) =.604; P = 0.616.

To get a more detailed understanding of what caused the differences in groups in the post- test to be significant, we performed Tukey HSD Post-hoc test. The post-hoc test showed there was a significant difference between the Cognitive Style group and all other groups in the post-test, but there were no significant differences between the other three groups.

The significant difference in post-test score between the Cognitive Style group and the Opposite to the cognitive style group was 2.58, (p = 0.005) See Table 9.2. The significant difference between the Cognitive Style group and the Traditional group was 2.07, (p = 0.046), and between the Cognitive Style group and the Modality group was 2.27, (p = 0.024). This result means that the cognitive style group benefited more than all the other three groups. On that account, teaching students in an environment that adapts to their cognitive style seems to help them to grasp the material more easily.

Time spent on the Library

The mean time (in minutes) that each group of students spent on the library is presented in Table 4 below.

Modality	Time (min.)	% Gain in test	No. pages viewed	Viewing time/page(min.)
CS	11.13 (2.80)	27.22 % (8.27)	4.58 (0.51)	2.43
OCS	11.01 (4.20)	8.89 % (12.50)	4.75 (0.45)	2.32
TRAD	12.45 (2.75)	18.67 % (7.57)	4.60 (0.52)	2.71
MR	15.26 (3.37)	14.67 % (7.57)	10.00 (2.83)	1.53
Overall	12.34	17.36	5.98	2.25

Table 5. Mean time in minute that students spent on the library, mean gain in test and mean number of pages viewed.

From Table 5 and Figure 3, it seems that students in the Modality group (MR) spent a much longer time using the IML (t = 15.26 min) than all other groups. However, the performance of this group was much less than the

BEST COPY AVAILABLE

performance of the Cognitive Style group. This Modality (MR) group viewed almost double the number of pages. The average amount of time MR students spent viewing a page was 1.53 minutes. This time was much less than the average amount of time students spent viewing pages in the other learning environments.

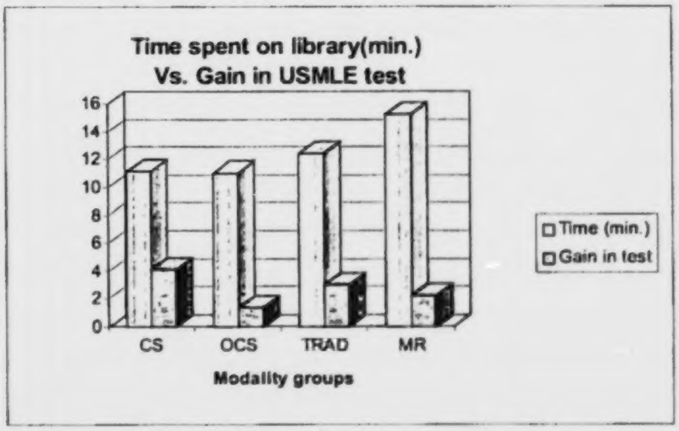

Figure 2. Time spent on library vs. gain in test in different learning environments.

ANOVA

		Sum of Squares	df	Mean Square	F	Sig.
PreTest	Between Groups	5.815	3	1.938	.604	.616
	Within Groups	128.367	40	3.209		
	Total	134.182	43			
PostTest	Between Groups	48.594	3	16.198	5.127	.004
	Within Groups	126.383	40	3.160		
	Total	174.977	43			
LIBTIME	Between Groups	124.049	3	41.350	3.676	.020
	Within Groups	449.895	40	11.247		
	Total	573.944	43			
Posttest-pretest	Between Groups	48.703	3	16.234	8.201	.000
	Within Groups	79.183	40	1.980		
	Total	127.886	43			

Table 6. One way ANOVA of USMLE tests and library time.

The results of the one way ANOVA in Table 6 shows that there was a significant difference in time spent on the library between the different groups F (3,40) = 3.676, p = .020. A Tukey HSD Post-hoc analysis was performed. This showed that there were significant differences in the amount of time students spent reading the material in the library between the Modality group and Cognitive Style group (Mean difference = 4.13 mins., p = 0.032), and also between the Modality group and the Opposite to the Cognitive Style group (Mean difference = 4.25 mins., p = 0.025).

Gain in test, amount of information viewed and time spent on Library

The ANOVA also shows there is a significant difference in the gain in the USMLE test (Post Test - Pre Test) between different modality groups F(3,40) = 8.201, $p < .001$. A Tukey HSD post hoc test shows that there is a significant difference in the amount of gain in the test between the Cognitive Style group and the Opposite to the Cognitive Style group (Mean difference = 2.75, $p < 0.001$), and between the Cognitive Style group and the Modality group (Mean difference = 1.89, $p = 0.017$), and also between the Traditional group and the Opposite to the Cognitive Style group (Mean difference = 1.67, $p = 0.041$).

Moreover, the ANOVA shows that there is a significant difference in the amount of information viewed by different groups F(3,40) = 37.14, $p < 0.001$. A Tukey HSD post hoc test shows that there are significant differences on the number of pages viewed between the Modality group and all other groups.

- The Modality group and the Cognitive Style group; Mean difference = 5.42, $p < 0.001$
- The Modality group and the Opposite to the Cognitive Style group; Mean difference = 5.25, $p < 0.001$
- The Modality group and the Traditional group; Mean difference = 5.40, $p < 0.001$.

The next section analyzes the modality group more deeply.

Modality Group

The results for the Modality group, in Table 7, shows that this group spent longer than all other groups in the library (t = 15.26min (SD=3.37)) but the average amount of time spent per page was much less than all other groups (t = 1.53min) and the gain in test score was less than the Cognitive Style and the Traditional group. Hence, we need to investigate number of questions such as how many pages students visited that matched their cognitive styles? and what was the average amount of time spent on these pages?.

Subjects	Total Time(min)	Total Pages Viewed	Modality Pages	% Modality pages	Time in Modality pages (min)	Time/ Modality page (min)	% Gain in Test
MR1	17.69	12	5	41.67	14.86	2.97	20.00
MR2	18.02	6	4	66.67	14.07	3.52	13.33
MR3	9.91	11	3	27.27	6.59	2.20	6.667
MR4	17.56	12	5	41.67	12.58	2.52	13.33
MR5	18.01	14	5	35.71	12.00	2.40	20.00
MR6	14.03	11	3	27.27	9.50	3.17	0
MR7	16.11	9	5	55.56	12.01	2.40	20.00
MR8	15.88	6	4	66.67	10.00	2.50	13.33
MR9	16.65	12	4	33.33	12.00	3.00	13.33
MR10	8.74	7	5	71.43	6.44	1.29	26.67
Total Mean	15.26	10	4.3	46.73	11.01	2.60	14.67

Table 7. Summary of the Modality group interaction.

In the previous section the results indicated that the students who were exposed to various types of representations (the Modality group) performed worse than the rest of the groups. This section investigates the Modality group in some detail. It examines the effect of just those pages viewed that matched students learning styles.

Table 7 shows that the mean percentage of the number of pages visited that matched the students' modality was 46.73% of the total pages viewed in the hypermedia library. The mean gain in the knowledge test was 14.67%

and the average time spent on this subset of pages, the Modality pages, was 2.60 min. per page. If we compare this Table with the previous one (i.e. Table 4), the overall average time the Modality group spent viewing a page was 1.53 min. We can summarize this finding as follows: Students in the Modality group were exposed to various types of representations and they tended to explore the learning material using various representations and they did not stick just to the representation that matches their preferences only. They shifted from one representation to another. Furthermore, they tended to spend longer time on the pages that matched their preferences.

Synthesis

The subjects in the Cognitive Style group learned significantly better than the other three groups. Providing students with a learning environment that adapted to their cognitive styles helped them to grasp knowledge more easily than without this adaptation. Giving students the freedom to choose the modality they was had from different representations did not seem to be as an effective method of teaching. The students shifted from one representation to another, as shown by the facts that the average amount of time spent per page was much less in comparison to the other groups and the proportion of pages chosen that did in fact match their profile was less than 50%.

From this study one can conclude:-

- Students accomplish deeper understanding of a topic when it is taught in a way that matches their cognitive styles
- Providing students with a rich environment in which they can learn a topic via their chosen modality seems not to be as an effective teaching method as automatically adapting the material.

The Usability of the Virtual Hospital Round

AlRawahi, Z. & AlShidhani, S.
Sultan Qaboos University
Sultanate of Oman
E-mail: rawahiz@squ.edu.om

Abstract: A usable instructional system is defined as a system that enables learners to accomplish learning goals or tasks in an effective and efficient way. This paper investigates the usability of Virtual Hospital Round (VHR) prototype, and explores medical students' and professionals' attitudes toward the VHR system. The evaluation of the prototype indicated that students and medical professionals liked and valued the program as a useful and enjoyable learning tool. The interface was mostly easy to use. The prototype stimulated learning and clinical reasoning.

Introduction

There are large number of methodologies exists for evaluating the usability and usefulness of information technology program. Oliver & Conole (1998) at the Open University developed a toolkit to help researchers in selecting an appropriate method for evaluating information technology program. The aim of this paper is to evaluate the VHR prototype. Thus, initially a brief overview of the prototype is provided. Then, the general usability method used to test the VHR is explained. Furthermore, the perceptions of medical professionals towards this type of learning environment and students' attitudes while working with the system are discussed.

Virtual Hospital Round

A Virtual Hospital Round (VHR) was developed for the domain of Cardiovascular diseases. The VHR prototype consists of an Interactive Hypermedia Library and a Cyber-Round. The Interactive Hypermedia Library enable students to explore a topic according to their learning style preferences. The Cyber-Round provides students with a simple simulated patient on which to practice clinical diagnostic reasoning abilities (AlRawahi, 1999). The design of VHR was influenced by Gardner theory of Multiple Intelligences (Gardner, 1983; 1993a; 1993b).

I. The Interactive Hypermedia Library

The adaptive Hypermedia Library contains study material (in several formats) about basic clinical science and the pathophysiology of diseases. As an implementation of Multiple Intelligences theory, the library web interface presents material in a set of different combinations of intelligences. The presented material can also be viewed according to traditional ways of teaching, or with multiple representations for comparison purposes. Figure I illustrate the VHR library interface.

II. The Cyber-Round

The interactive Cyber-Round section is a practice-based learning tool in cardiovascular diseases, where learners can explore one or more clinical cases. Students are provided with a rich virtual environment to practice medicine similar to the actual hospital round. They are given a simple, simulated patient with which to practice clinical skills. The system tracks students' progress while they work with the simulated patient. They can start by taking the patient's history, selecting from a menu. They then can choose to

- ☐ Perform a physical examination (using a mouse to click on an interactive patient image),
- ☐ Hypothesize a differential diagnosis,
- ☐ Request laboratory or radiological tests, and/or
- ☐ Diagnose the patient.

To resemble the hospital rounds and to give a sense of reality, students are given a reasonable amount of freedom to perform the task, according to their intuition, as they would in a real situation. Figure II illustrate the Cyer-Round interface.

This is a 64 year old man with chest pain.

- Imagine your self now taking the history of the above patient
- Select suitable questions in a logical order

Do you wake up from sleep due to this problem--

Dr. How long have you had this pain?
Patient: About two months ago I started having this pain.

Dr. How often does it come on?
Patient: I had this pain 2 times last month when I was angry, but it went away.

Dr. Do you wake up from sleep due to this problem?
Patient: No.

Dr. Do you have chest pain with shortness of breath?
Patient: Yes.

Dr. Do you drink alcohol? How much? Since when?
Patient: Sometimes.

Figure II. The Cyber-Round Interface (History taking session)

General system usability

Generally, researchers in the area of system usability define a number of usability criteria which must be met when designing a usable system. The PLUME (Browne & Simpson,1996) system encompasses most essential elements of testing an interactive learning environment, so it was used as a general evaluation method for the VHR prototype. The PLUME system emphasizes that a usable system must embrace the following characteristics: productivity, learn-ability, user satisfaction, memorability and a low error rate.

This section gives an overview of the definition of the different PLUME elements:

A. ***Productivity*** - a productive system is a system that enables learners to carry out the learning tasks quickly. This is important in clinical education, since medical students are busy and normally tend to discard most noncompulsory duties. Providing them with a productive system that helps them to process their learning more quickly is a necessity. Therefore, it is crucial to evaluate the productivity of the VHR.

B. ***Learnability*** - a learnable system is a system requiring little training. If systems are easy to learn and match the way the learner approaches a task, this will enhance learning.

C. ***User satisfaction*** - learner satisfaction motivates students to spend a longer time with the system, to learn and understand more.

D. ***Memorability*** - if system processes are memorable, learners will require less training and will be able to return to maximum levels of performance more quickly after absences.

E. ***Low Error Rate*** - a measure of the accuracy of the work carried out to complete tasks.

Method

11 fifth year medical students and 3 medical professionals with a minimum of three years experience as a general practitioner filled in a general usability questionnaire after they had worked with the VHR prorotype. This questionnire (see Appendix) was very short and simple and invited respondents to assess the system against the five PLUME criteria. It concentrated on the main system usability elements as discussed above. The users were given an explanation of each usability element and then they were asked to rank each element from 1 (least usable)-10 (most usable).

Results

The average for each element was calculated by summing up students' responses to the usability questionnaire and dividing it by the number of subjects. Then the percentage score was calculated by dividing the average score by the maximum score (10). Table 1 presents the main findings from the usability study. As indicated in this table medical students seem to value the prototype more than medical professionals.

Medical professionals assigned 80% for the VHR's productivity. While, medical students assigned it 91%. Regarding prototype learnability, medical professionals gave it 78% while medical student gave it 83%. Moreover, the satisfaction of medical professionals was 83%, while the satisfaction of medical students was 95%. Medical professionals estimated the memorability of the VHR prototype as 80%, while medical students thought it was worth 85%. Finally, the estimate of low error rate when using the prototype were given by medical professionals and medical students as 75% and 80% repectively. The higher the percentage of the error rate indicate that students had less difficulties or frustration working with the protoype.

PLUME Metrics	Medical Professionals	Medical Students
Productivity	80%	91%
Learnability	78%	83%
User-satisfaction	83%	95%
Memorabilty	80%	85%
Error rates	75%	80%

Table 1. Findings for the general usability elements.

Medical professionals' perceptions of the VHR

This section reports on medical professional's attitudes towards the usefulness and effectiveness of VHR as an instructional system.

Method

Initially, three graduate medical professionals were given a brief summary about the main objectives of designing the VHR and this evaluation. Then they were shown how to work with different sections of the VHR prototype. After that they were asked to work with the prototype and to examine its contents and functionality. They were asked to comment about the following:

1. The level of the material presented in both the adaptive medical hyper-media library and in the CyberRound cases;
2. The accuracy of the material presented in both the adaptive medical hyper-media library and in the CyberRound cases;
3. The degree to which the program would motivate learner to learn more about the topic;
4. The degree to which the program would help students to practice clinical reasoning skills;
5. The implementation of the various teaching methodologies;
6. The comparison between the VHR and the OSCE study material;
7. The value of the program as an educational tool;
8. What they liked and disliked about the program;
9. Any suggested modifications or improvements.

Results

The results of their input on the level of cases and material embedded in the VHR prototype indicated that Dr. H and Dr. N thought the level of material would suit 5th year medical students, while Dr. T thought that it was most suitable for 4th year medical students. Regarding the accuracy of the materials Dr. N believed that 85% of the material were accurate, while Dr. H felt 82% was accurate, and finally Dr. T assigned 80% for information accuracy.

Would the program help students to practice clinical reasoning skills?

The three medical professionals believed that the program would help students to practice their clinical reasoning skill through their exposure to authentic cases in a simulated environment. They thought the main advantage of these simulated cases was that they would guide students to practice the whole clinical reasoning process. For example, students could follow through on a simulated patient, including ordering lab tests.

While, medical students think the program is helpful in a way that if a mistake was made it will not be on a real patient. Medical students thought this point might help them to feel calm when practicing, while normally students feel uncomfortable or frightened.

Implementation of teaching methodologies

The medical professionals were pleased to see different representations in the learning environment. They believed these representations were very useful for medical students. All of them liked the visual-linguistic representation most and they appreciated the other representations. Two of the medical professionals thought that allowing students to choose the representation they prefer from among the representations (multiple modality group) might confuse students and might cause loss of concentration.

Comparison between the VHR, the OSCE study material and real clinical teaching

The three medical professionals were asked to compare cases in the VHR with objective structured clinical examination (OSCE) cases. The cases in the VHR prototype were judged to be similar to the OSCE and case-based learning, but did not compare with actual physical examination training because of the need to palpate, and the need for percussion and auscultation. Furthermore, the three medical professionals believed that the cases in the VHR outperformed the OSCE and short cases in its method of history-taking and on the general management of a patient in terms of clinical reasoning for a given problem.

The value of the program as an educational tool

All three subjects believed in the value of the prototype as an effective educational tool for clinical practice. Furthermore, they highlighted that the main advantage of the simulated patients as always being available, unlike real patients. Moreover, they believed that computer based learning tool motivate students to review notes, books and discuss the case with a tutor or peer while solving the case. In their view, this is normally difficult when working with a real patient, as students in real practice need to think and act spontaneously.

Suggestions for modifications or improvements

The medical professionals suggested that immediate feedback on every step while solving the clinical case is needed, especially when users (medical students) act erroneously. Moreover, they wanted the patient management part to be implemented.

Discussion

This section summarizes results of the medical professionals' evaluations of the prototype. The results show that they believed that the VHR prototype would be an effective and efficient multimedia learning tool for fifth-year medical students. Moreover, they were satisfied with the content and functionality of the prototype. For instance, one subject liked the cases in Cyber-Round as case-based learning, and stated that the VHR might help medical students in their fifth year preparing for an M.D. examination. This is because medical students often waste time in hospitals finding cases to practice on before an examination. It was thought that the adaptive medical hypermedia library section would motivate students as they were getting information in different representations. The other two subjects thought that the cases in Cyber-Round would act as a useful tool for practicing history taking and clinical reasoning skills before going to the ward. Furthermore, they believed that the cases would be very helpful as preparation for clinical examination.

All three medical professional subjects liked the fact that the VHR prototype allows practice with all aspects of clinical reasoning activity, because in a clinical setting students rarely get to practice the whole process. Finally, the subjects hoped that the treatment and management portions of the prototype would be implemented.

Medical Students' Perceptions and Attitudes Toward the VHR

Medical students were observed using the prototype. Notes were made on students' attitudes towards the system while observing them carrying out general actions. Moreover, 12 students were interviewed and data gathered about their perception of the usability of the VHR prototype. Items discussed included perceptions of the importance of the program as a learning tool; perceptions of different tasks and their affect on problem solving; how the prototype compared to a real teaching round; and likes and dislikes regarding the system along with suggestions for modification.

Method

Students were asked to solve two clinical cases as they would normally do in actual clinical practice. In addition, while they were working with the prototype they were asked to think aloud and to verbalize what they were doing and why they were doing it. They were observed while they were working with the prototype and notes were taken on their general actions executed and on their impressions while working with different parts of the prototype. As the subjects were very busy and they were already spending a long time doing the experiment voluntarily, it was difficult to get many of them to fill out the usability questionnaire. Therefore, we carried out the usability evaluation as a conversation (informal discussion) after students had finished working with the prototype.

Results

- 92% felt the program was easy to navigate, while 8% felt the program was very easy to navigate.
- 80% felt the program did not require initial training, while 12% felt training might be helpful and 8% felt training was needed.
- 84% thought the program was interesting and forced them to think and to reflect on their knowledge.
- The only difficulty students faced was identifying the questions to ask in the history session and certain types of tests in the investigation session. The reason for this was that the pop-up menu was filled with a large number of items.
- Students believed that they learned from the program, and they felt the program was an effective educational tool.
- Students appreciated the opportunity to practice gathering information and working with a patient problem from beginning to end.
- Students reported that the prototype helped to test their existing knowledge, and to identify knowledge limitations.
- Students reported the VHR helped them practice reasoning throughout a patient case and helped to sharpen their thinking processes. The program 'forced' them to diagnose the simulated patient. The diagnosis process was less distressing than actual clinical practice.
- Students wished the system provided feedback on their actions.
- Students wished the management part of the system was implemented.

Synthesis

The study found that students liked and respected the program as a valuable learning instrument. Most students agree that the interface was easy to use. The VHR prototype motivated learning and fostered students' clinical reasoning skills. Students thought this type of practice gave them the chance to work through the case independently, without relying on a tutor who might be busy, and without relying on a real patient who might be unavailable, busy with other students, or in a state that students cannot use for practice.

The study found that medical professionals were satisfied with the value of the program as an educational tool. They thought that students could learn through practice and apply their knowledge by free inquiry with the simulated patient. Students could identify their own limitations in knowledge. This would motivate them to search for knowledge in the interactive hypermedia library of the system. Finally, computer patients are handy at any time and location, while real patients may not be.

Abstract:

This paper focuses on aspects of e-government with emphasis on how local authorities are coping with the transition into the Information Society. E-government will be reviewed in the light of such topics as social inclusion, security and e-democracy. The challenge has been set in the UK, for local authorities to deliver 100% of services capable of electronic delivery by 2005, with 25% to be delivered by 2002. The research was carried out with the support of a local authority council in South Yorkshire. It included a survey of members of Northern Authorities Benchmarking IT (NABit) to ascertain views on various aspects of e-government. The results were analysed to provide a more valid representation of local authorities' attempts to reach the 2005 target. The findings challenge some of the views portrayed in the literature review and show low confidence in achieving government targets. eLearning emerged as a key factor to prevent social exclusion and guarantee e-democracy.

Introduction

The information society could be seen as *"a world where it is possible to access vast quantities of information on demand and to transact remotely"* (Lampard, 1997:180). This quote emphasizes the view that the Internet is removing distance as a factor in many transactions and conversations. Mulquin (1998) thinks that the term "information society" is misleading because people want communication more than they want information. However, despite the fact that since the advent of email the desire to communicate appears to be greater than ever, it does not necessarily follow that people want correspondence more than they want particular facts and figures. It seems that the more access to information people have, the more access they want, which increases the relevance of the term, "information society". Mulquin (1998) also uses the phrase *"the death of distance"* but this does not reflect the fact is that most people live their lives on a local scale and are therefore most likely to be interested in local activities, businesses and information.

E-Government in the UK

It is in this context of the Information Society that the UK government has stated its commitment to providing better services for the public, and it is the citizen that is at the centre of the change. Departmentalism has characterised government for a long time and e-government seeks to challenge these rigid structures. Governmental demarcations have lead to inefficiency for the customer, as well as a frustratingly slow pace for those working within the sector. This research revealed that local authorities are aware of the necessity to break down this "silo effect" in order to create more flowing information systems and practices. However, the implementation of the required change process is being hampered by existing systems, for example, a top-down organisational structure of local authorities prevents the very change that needs to take place. Nevertheless, local authorities are aware of the need for a culture change, which is the first step in actually making the changes happen.

Academic literature has embraced the ideal of e-government. Generally, the ideas about e-government are similar, i.e. that it will revolutionise the way the government transacts and interacts with businesses,

BEST COPY AVAILABLE

citizens and other areas of government. In fact, it is thought that e-government will impact all aspects of an organisation, from the highest level down to the customer as an individual. However, although predictions for e-government in the UK appears to be optimistic, these initiatives are still in their infancy and it will take much longer for problems to be identified and resolved. Much of the literature at this point is somewhat theoretical and sparse, and any firm conclusions at this stage are likely to be later challenged.

Currently, Central Government stresses the need for Local Performance Indicators for Best Value. Evidence from this research would suggest that this has been taken on board, with the majority of authorities questioned using their own indicators. This is in line with the Audit Commission's recommendation mentioned in the literature review. However, if measured alongside the results from the question of whether the authorities thought that they would meet the 2002 and 2005 targets, some Local Indicators are not as effective as they might be, since the majority of authorities are not confident of achieving the 2002 target. Most authorities were confident of achieving the 2005 target though, which suggests that indicators may have been implemented too late in some authorities for them to make a big enough difference to the 2002 target. However it must also be remembered that these indicators are for guidance only and may not be as relevant to the targets as the results suggest. Evidence from the interviews conducted stresses some frustration over the changing of Best Value Performance Indicator 157, which might have caused some authorities to have to change or update their own indicators and cause delay in working towards their targets.

Electronic Service Delivery as a Form of e-Government

Overall it seems that the UK government is pushing for Electronic Service Delivery (ESD). There are already countless projects aimed at getting local authorities to bid for money to implement technological solutions. This may hide the real need for cultural change in local authorities organisations and structure in order to support and endorse ESD. Technology and cultural change have to work interdependently and even though this change process is apparently taking place, more will need to be done to change attitudes and ideas in local government.

As far as the development of e-government goes, there is certainly a good deal of progress being made, although not always at the level or speed that the government expects or claims it to be. Although the literature is very biased towards the benefits of e-government, the potential dangers are also highlighted and it is understandable that such a new form of government is seen as exciting at this stage. It will most likely be a few years down the line that mistakes and problems will be recognised. One problem that does need to be addressed is the need to train people in the new skills required in this new society so that they understand the uses of Information and Communication Technology (ICT).

Moving Towards E-Democracy

One of the major pillars of the Information Society, and the change process that is taking place in central and local government, is the need for consultation with the citizen. E-democracy therefore, has the potential to provide a forum for consultation processes. It is predicted that voting and voter registration will be carried out online in the next few years (DTLR, 2001), although while authorities appear to be concentrating on working towards other objectives, this could be a doubtful target at the moment. On the other hand, the advent of digital television, the opportunity to vote and ease of doing it from one's armchair, thus helping to increase public participation, might just make the 2005 target achievable. Nevertheless, it should be noted that voting is not the only cornerstone of democracy or e-democracy, but that ESD, associated with access to local and national politicians, is also imperative.

Councillors are taking tangible steps towards e-democracy, with many having email addresses so that citizens can voice their concerns/problems to a person, rather than a department. This should make the local councils more aware of people's concerns as well as making them answerable to their constituents. The literature on e-democracy highlights the need for the citizen to be part of the consultation process, but it does not seem likely that democracy will increase dramatically unless the other issues are addressed too.

However, all dreams of e-democracy may be at risk if the citizen is not prepared to make use of ESD services. The phenomenon of the non-networked citizen will tend to deepen the socio-economic divide.

Social Inclusion vs. the Digital Divide

There is a great deal of literature that confronts the ever-increasing problem of social exclusion and the threat of a "digital divide", not just concentrating on what the government is or should be doing, but its nature and possible consequences of this divide. Social exclusion can be defined as:

> *"What can happen when people or areas suffer from a combination of linked problems such as unemployment, poor skills, low incomes, poor housing, high crime environments, bad health and family breakdown. In the past, governments have had policies that have tried to deal with each of these problems individually, but there has been little success at tackling the complicated links between them, or preventing them from arising in the first place."*
>
> Stoker, (2000)

In 1997, the UK government set up the Social Inclusion Unit, with a remit to help improve government action across departmental boundaries to combat social exclusion, thus at least addressing the issue. As one of the principles of e-government is to challenge social exclusion, the UK government's Policy Action Team (PAT15) published a report in March 2000 entitled "Closing the Digital Divide" in which it announced a £252 million initiative to increase access to the emerging technologies.

The following statement shows that the government has indeed recognised the danger of the digital divide:

> *"We cannot risk leaving behind people living in our poorest communities. We must close the digital divide so everyone can reap the benefits of living in an e-nation. Government, business and voluntary and community organisations must work more closely together to help achieve this aim."*
>
> Department for Trade and Industry (2000).

Despite the fact that the report was written over a year ago, so far there has been no evidence that any goals set out in the report have actually been achieved. The report only stated new technologies were needed to help disadvantaged groups and did not elaborate on how these ideas should be actually implemented. Thus, whether or not the government will succeed in fulfilling its promises will be only seen in 2005.

Internet Access in the UK

The government claims that Internet use is growing rapidly (DTLR, 2001), although it recognises that there is still a divide between those who do and do not have access. Symonds (2000) produced a table showing the percentage of the population with Internet access in 2000, with Britain ranking eleventh out of the 31 countries examined, behind the US, Canada and Singapore, all leaders of e-government. Furthermore, in a report by the Centre for Analysis of Social Exclusion, Duffy (2000) presents the results of a survey that show that 71% of the respondents from deprived areas had no access to CMC technology at home or work. This may sound a significant figure. However, the findings of the same Social Exclusion report indicate that Internet/email is the least attractive medium for gaining information by the majority of people living in deprived areas. This being the case, it appears that although people may indeed have access to appropriate technology, often they are simply not aware of it and do not have the appropriate skills to use it.

In support of this, Booz, Allen & Hamilton (2000) proposed that Internet penetration should be above 70% for e-government to be considered a success and to prevent the development of a digital divide. Since this figure has not yet been reached, there is clearly some way to go before Britain achieves the desired level of Internet access. Stoker (2000) considers that the lack of computer equipment will not be the major factor preventing some people from access to online services, since digital television will provide access when it replaces analogue television in 2008. Nevertheless, cost for telecommunications equipment (for example obtaining sufficient bandwidth for mobile phone users) could well hamper further growth of Internet use. Furthermore, if insufficient use of the Internet is indeed due to lack of awareness, as well as lack of skills, then the reason for educating citizens regarding the uses and benefits of ICT is immense.

Addressing the Digital Divide: Access versus Education

Symonds (2000) argues that the digital divide is **not so much a question of access but of education**. The government is addressing this, for example the National Grid for learning is intended to provide access to the Internet for all UK schools. Other initiatives such as Learndirect, focus on empowering the socially excluded to take advantage of the opportunities offered by the "e-revolution" (DTLR, 2001). The Booz, Allen & Hamilton (2000) report also stresses the need for Internet skills to be part of the national curriculum. However the community members who have left school would still not be prepared to use ESD services. Thus, adding a new component to social exclusion, based on a generation gap. It is proposed that one possibility to address this new divide would be to assign a new role to younger members of the community who would then influence and educate their elders in the benefits of ICT. Nevertheless, and in the short-term, the government has to assume responsibilities in preparing the citizen for E-government, namely through e-Learning initiatives and encouraging Lifelong-Learning.

The Case Study

The overall aim of the research was to examine the current status of e-government, focusing at the local level. The research itself was carried out with the support of the Rotherham Metropolitan Borough Council (RMBC), South Yorkshire, UK and included a survey (questionnaires and interviews) of local authority members of NABit (Northern Authorities Benchmarking IT).

15 questionnaires were sent out to NABit members to ascertain thoughts and views on various aspects of e-government, both of the authority's own progress as well as personal thoughts. The results were analysed along with interviews conducted with members of RMBC to provide a more valid representation of local authorities' attempts to reach the 2005 target. Throughout the research a conceptual model has been used and referred to. The findings from the interviews and work experience at RMBC in particular challenge and update this model. The findings, along with the discussion and conclusion challenge the results of the literature review and show that out of all respondents, confidence in achieving targets is not as high as the government is projecting. Although progress is being made towards full ESD as a significant aspect of e-government, it is a slow progression.

The first objective was to examine the literature to discover information on and gauge reactions to the concept of e-government. In support of the research, literature regarding proposed e-government targets and ideal status was scrutinized. This revealed that the government has generally commissioned the reports that have been written, indicating a lack of independent research. Possibly one of the reasons for the lack of literature is because this area is constantly changing and evolving and any piece of work will quickly become out-dated. Perhaps after the 2005 target, more academic literature will emerge.

The second objective of the study was to examine RMBC and other local authorities' approaches to e-government, their future targets and perceived reasons for successes and failures. The research instruments used were successful in that they challenged the issues raised in the literature and indicated that not all authorities were achieving as much as others, those that the government highlights as being "beacon councils". The research investigated the results and outcomes of the latest projects and ideas for the progression towards the UK government's 2005 target.

The response rate received for this research was very good, although due to the relatively small sample size, it can only provide an indication of progress of e-government and since this was a small-scale piece of research, inferences, rather than conclusive deductions, have been drawn from this study.

The Research Findings

The survey discovered that direct online access to members of the authorities is one of the largest growth areas, suggesting that authorities are taking the need for citizens to have a different channel to voice their opinions seriously. The authorities that responded to the questionnaires felt that Internet penetration in public areas was increasing, which suggested that public access was increasing, as well as more focus on the skills necessary to use the Internet. Whether this is being achieved across the country would require a much more involved project, but the results obtained, along with the literature would suggest that the problem of social inclusion is to some extent being addressed. This recognition at least shows that the government is maintaining its awareness of the problem, but it also shows that the attempts to decrease this divide is not working as well as was hoped. However, the rapidly developing nature of the Internet means that it is very difficult for all involved to keep up to date with the latest developments.

The information about Pathfinder projects from both the literature and survey suggests that the government already had a view of an ideal pathfinder. The results from the questionnaire suggest that the bidding process had not been perceived as successful in terms of feedback received, either for bids that had been accepted or for those that had not. The questionnaires revealed that a number of participating authorities believed their bids failed due to larger and higher-status authorities receiving more money. The interviews conducted as part of the research also revealed a similar attitude, although the reason for these strong feelings from authorities could be due to resentment from a failed bid.

The research examined targets for local authorities and discovered that the government is very keen on promoting these projects but is frequently failing to provide the support needed at the local level. One of the most significant problems revealed by this research, is that the lack of funding to local authorities is hampering their chances of success. South Yorkshire is a region that has suffered a great deal with its declining basic industries over the past 20 years and even though the Objective 1 Funding has been granted into the region, funding still requires bidding, taking up time and resources which could be better spent.

The questionnaire has indicated that there is sufficient direction from the government about all of the changes that are due to take place, but the problem occurs when the local authorities actually receive the information. The evidence from the literature would suggest that the problem could be that disseminating the information around the authority is hampered by the very nature of local government. If this is the case, there needs to be a huge drive by the authorities to change their culture and make change happen. The findings suggest that involving citizens in the consultation process may be adapted and implemented at the local level, although it is not possible to say when.

The assistance of RMBC in this research has been invaluable. This enabled an in-depth examination of one authority's approach to e-government, which helped to validate the reliability of data collected from other NaBIT members. One of the most useful things about working within the council authority was gaining an awareness regarding the nature of local government and the frustrations that occur. Although this type of action-research approach could be said to cause problems of bias, working within this organisation enabled a greater insight into e-government at a local level than a simple literature review could do.

Conclusions

Worryingly, towards the end of the research period, the Guardian published an article on the 16th of August 2001, stating that the ESD targets were failing to be met. This article discusses the announcement by Andrew Smith, Chief Secretary to the Treasury, that the target of having 90% of routine goods and services online had been missed and was apparently less than half than expected. If this is true, what other failures can be expected along the way? Although progress towards the "information society" is increasing in pace, it seems the UK government needs to reassess its targets and closely monitor the real situation. The IEG statements might help, but even it may only be an empty gesture, since local authorities might prefer to be involved in more short-term projects and plans. The Guardian's article hints that the government is backtracking on its targets, downplaying their previous significance and that there is a real need to broaden significant participation. Perhaps this is the time for more literature on the field of e-government to emerge. It is now imperative that more clarity on e-government issues is provided and government bodies demonstrate a more responsible attitude

Abstract: Appalachian State University (ASU) is a participating institution in the North Carolina Consortium for Distance Education in Communication Sciences and Disorders (CSD). This Consortium initiated a successful distance education masters degree program in 1997. Eight indicators of success are presented, including low attrition rate, indicators of student satisfaction, and data showing equal to superior performances of distance students in competition with traditional on-campus students.

Introduction

Appalachian State University (ASU) is a participating institution in the North Carolina Consortium for Distance Education in Communication Sciences and Disorders (CSD). This Consortium initiated a successful distance education masters degree program in 1997. This paper will present multiple evidences of that success. Other distance education programs may wish to conduct program evaluations with many of these measures.

Structure of the Consortium

The North Carolina Consortium for Distance Education in CSD offers a masters degree to public school speech-language pathologists (SLP). This mission was a response to legal action by the North Carolina Board of Examiners to require enforcement of a North Carolina Department of Public Instruction policy that all SLPs employed in the state's public school systems hold a masters degree in communication sciences and disorders, in accordance with guidelines of the American Speech Language and Hearing Association (ASHA). In 1996, the North Carolina Supreme Court upheld a North Carolina Court of Appeals ruling that public school SLPs who began that employment at the bachelors level after 1982 must obtain a masters by the year 2000, and that bachelors level SLPs who began employment in 1982 or earlier must also earn a masters degree in order to be eligible to continue working as public school SLPs after July 1, 2005. The imposition of these deadlines added urgency to the Consortium mission.

The five universities of the University of North Carolina System that participate in the Consortium are Appalachian State University, North Carolina Central University, University of North Carolina at Chapel Hill, University of North Carolina at Greensboro, and Western Carolina University. Each of these universities offers a masters degree in CSD, and each developed a corresponding distance education masters program in support of the Consortium efforts. Each of the five participating universities requires its distance education students to meet all of that school's requirements for this degree, and students receive their degrees from the universities in which they enrolled. The major function of the Consortium is to organize and facilitate distance delivery of a common set of core courses, so that Consortium students are able to complete distance coursework during the school year while maintaining their employments in the North Carolina public school system. Other functions of the Consortium include publicity, recruiting, and providing a support system for the students enrolled in the distance education Consortium.

Students and Distance Education Courses

Only public school SLPs are eligible to participate in this program. Students have enrolled who work in counties scattered throughout the state of North Carolina, including counties on each of the four borders of the state. Distance courses may be taught by any of the five participating university programs, and are telecast to as many as three interactive sites throughout the state. Those students who are within one hour's drive of the originating university or an interactive site are expected to attend classes at that site. Students who are more than a one-hour drive from an interactive site are provided videotapes of lectures; these videotapes are sent to those students within a few days after each class. Variations in this course delivery plan have been used for some of the more recent course offerings. Some courses are now being made available by videostreaming, and one of the authors is using a more web-based approach supported by editing videotapes of classes from previous semesters to produce a CD-ROM that is provided to students upon enrollment.

At ASU, the CSD masters program is 60 credit hours; the requirement at other Consortium universities varies from 54 to 63 credit hours. At least 36 of those credit hours are from coursework, but as many as 24 credit hours are required in clinical practicum experiences. ASU requires four one-semester clinical experiences, and a full-time internship during the summer or semester prior to graduation. Students are required to attend two eight-week summer sessions to obtain their first two clinical practica. During each of those two summers, they can also enroll in as many as nine credit hours of academic coursework. Some students have already completed as many as six appropriate credit hours prior to admission, so the average student completes approximately half of her academic courses by distance.

Therefore, the distance education program at ASU is actually a hybrid program, providing the opportunity for comparison of performances in on-campus vs. distance courses by individual students. In addition, comparisons of distance students and students enrolled in the traditional on-campus program are possible in summer courses in which both types of students enroll. Since most distance courses are taught in conjunction with on-campus sections of those courses, an additional evaluative comparison is possible.

Results of a Distance Student Opinion Survey

In 2001 a survey was distributed to fifteen program graduates and twelve students nearing graduation. Twenty usable responses were received; this high response rate is likely the result, at least in part, of indicating that the names of respondents would be entered in a drawing for a $25 gift certificate. Some survey questions were designed to obtain background information such as the number of courses that the student had completed by distance and the number completed on campus. Two survey questions designed to elicit comparative opinions regarding distance vs. on-campus courses asked students to list the courses they had enjoyed the most, and to list the courses in which they felt they had learned the most. Then they were asked to circle those courses that they had taken as distance courses. This noting of distance courses was checked against academic records to insure that the method of course delivery was reported correctly.

Table 1 shows the number of courses taken each way (distance vs. on-campus), the number of each listed as courses the students enjoyed the most, the number of each listed as courses in which they learned the most, and the results of paired *t*-test comparisons of these responses. Although not statistically significant, students listed almost twice as many distance courses as on-campus courses as the courses in which they had learned the most. This result leads the authors to believe that students did not consider distance courses to be less rigorous, nor did they consider their learning to be hampered by taking those courses at a distance. If they had experienced significant frustrations with distance coursework, those frustrations were not reflected by their opinions of comparative learning. Other questions on the survey asked respondents to write about problems encountered in each group of couses; their written responses to these questions did not reveal major differences.

Mean Number of Courses	Distance Courses	On-campus Courses	Paired 't'	p-value
Completed	7.28	7.83		
Chosen as most enjoyable	1.61	0.67	2.29	.035
Selected for most learning	1.59	0.88	1.32	.20

Table 1: Results of an opinion survey of twenty distance education students regarding enjoyment of, and learning in, distance courses.

The statistically significantly greater number of distance courses chosen as courses enjoyed the most supports a conclusion that this distance program has been successful, at least in terms of providing distance coursework that does not alienate distance students. There are three confounding factors specific to this program that might contribute to the selection of distance courses as those courses which students enjoyed the most. One is that many of these students have families, and they get to live at home while completing distance courses. Secondly, students can look forward to continuing in their chosen careers, and they realize they would not be able to do that without giving up their paychecks were it not for this distance education program. Thirdly, these students apparently enjoy their work as public school SLPs, and the sense of accomplishment and contribution they receive when they are actively working at that job may contribute to their general satisfaction level.

Even though the three possible confounding factors presented above would seem to make it more likely that students would choose distance courses as courses they enjoyed the most, there is a major reason why that is still surprising. Working as a public school SLP is a demanding and exhausting occupation. Most of the early graduates of this distance program were facing year 2000 deadlines, so they enrolled in two distance courses each semester. The workload of two distance courses took away a huge percentage of their personal, family, and even rest and relaxation time. The Consortium leaders were continually amazed at how students were able to keep up with their distance courses while working full time and dealing with the usual problems of living (Cochenour, unpublished). The fact that they tended to receive lower grades in distance courses than in their on-campus summer courses, as shown in Table 2, probably reflects the demanding workloads they faced while taking distance courses. Still, they more often chose distance courses as courses they enjoyed the most, and they chose distance courses as courses in which they learned the most at least as often as they chose on-campus courses.

	Distance students GPA	On-campus students GPA
Summer 1998	3.817 (54)	3.836 (605)
Summer 1999	3.995 (105)	3.864 (503)
Summer 2000	3.833 (54)	3.858 (333)
Total for 3 summers	3.894 (213)	3.851 (1441)
Distance courses	3.471 (291)	

Table 2: Grade point averages (and credit hours) for thirteen ASU distance students in distance and on-campus courses and corresponding data for traditional students at ASU.

Comparative Performance in Summer Courses on Campus

Mean GPAs for summer courses taken by ASU distance students are shown in Table 2, along with the mean GPAs in the same courses for on-campus students. There was no significant difference in mean GPAs of distance and on-campus students when enrolled in the same summer courses, but the mean for distance students was numerically higher than the mean for on-campus students. This is surprising because distance students had significantly lower admissions scores than on-campus students (Barber, 2002). However, both age differences and public school experience may have impacted this performance. Distance students would have had a number of years of practical experience during which they probably researched problems and issues that they faced with their case loads in the public schools. The years of experience of ASU distance students included in this data ranged from three to thirteen.

However, the age difference might work both ways. The older distance students regularly describe feeling paranoid about their ability to compete with students who have not had long breaks in their education, or they simply state they are afraid they can't do as well as younger students. Part of their fear may be that they did not have a high undergraduate GPA, so they lack faith in their academic abilities. In fact, a low undergraduate GPA may have been one of the factors that led to their decisions not to pursue the masters degree immediately upon receiving their B.S. However, the age difference may actually contribute to their performance if they are more mature, more determined, and less likely to invest a significant amount of time in social activities. Even their insecurity about competing with younger students may spur extra efforts.

So the Consortium distance education program is successful in terms of selecting students who have the ability to succeed in on-campus coursework. These students have also been successful in their clinical practicum and internship assignments; this is another indicator of program success.

Distance Course Performance

One of the authors taught a course which utilized three different content delivery modes. A group of on-campus students completed the course in a traditional classroom format. A second group of off-campus Consortium students completed the course by viewing videotaped lectures. A final group of on-campus students completed the course utilizing the distance format used by off-campus students. The mean scores of students in all three groups on a written comprehensive exam were not statistically significantly different, and, in fact, were almost identical (Table 3). Thus, distance students were as successful in this course as on-campus students completing the course in a traditional format or using distance technologies.

Group	Instruction Method	Number of students	Mean Score
On-campus students	classroom	35	90.93
On-campus students	distance	31	90.28
Distance students	distance	22	89.72

Table 3: Comparative performance on a written comprehensive exam of distance education students and on-campus students in a Dysphagia course.

Goal Achievement

The goal of the Consortium distance education program was to provide public school SLPs the opportunity to earn a masters degree without interrupting their service to the public schools of North Carolina. A total of sixty-three (63) students have entered the Consortium program. Only five of those students have left the program, and one of those five transferred to the on-campus program so that she could complete the masters sooner. Another decided to move back to her home state of New York, and she has entered an on-campus graduate program there. So our dropout rate has been below 10%, in contrast to the high drop out rates of many distance education programs. The authors consider the low attrition rate to be another indicator of success of this program.

A total of thirty-one (31) students have completed this program and earned their masters degree. Most of those graduates have continued to work in North Carolina public schools after graduation. There is a shortage of qualified SLPs who would have been available to work in these public school positions if the Consortium students had not been able to continue to do so during their masters program and upon completion of that program. So very few of their school systems would have been able to find replacement personnel in a timely manner. It is not possible to calculate the number of children in need of speech-language therapy who would not have been served had it not been for the Consortium program, but the actual number has to be thousands of child-years. The success of this program can also be expressed in terms of high graduation rates, in terms of enabling the public schools of North Carolina to keep employees that they knew and wanted to keep, and in terms of the number of children in need of speech-language therapy who would have not been served if it were not for this program.

A Major Reason for the Success of This Program

Not all distance education efforts are successful, and few enjoy the level of success of this program. There is little question that the North Carolina Consortium for Distance Education in CSD has enjoyed this level of success because its students are mature and very highly motivated. The prospective students who sought admission to this program were those public school SLPs who wanted to continue in this career. The fact that they could not do so without successfully completing a masters degree program provided huge incentives that resulted in superhuman efforts. While Consortium planners and faculty made the program workable, it has been student efforts that actually made it so incredibly successful.

Summary of Indicators of Success of This Distance Program

1. Five North Carolina universities have cooperated in a Consortium effort to share the teaching, delivery, and operation of a distance education masters program. That Consortium effort is entering its sixth year of course offerings, and it is still viable.
2. Students who have taken approximately equal numbers of distance courses and on-campus courses more often identified distance courses as the courses they enjoyed the most. They also identified distance courses as the courses in which they learned the most at least as often as on-campus courses.
3. Performance in on-campus summer session courses by students enrolled in the Consortium distance education program was equal to performance in the same courses by students enrolled in the regular on-campus program, despite the fact that distance students had significantly lower admissions formula scores.
4. When given exams over the same course material, students receiving instruction via distance delivery performed as well as students in on-campus sections.
5. The Consortium distance education program has a very low attrition rate, and promises to have a very high graduation rate.
6. SLPs working in North Carolina public schools have been able to maintain employment while earning a masters degree. Further, most have been able to earn that degree prior to a deadline that could have resulted in the loss of their jobs.
7. Many North Carolina public school systems have been able to keep employees that they know and value, rather than having to try to recruit replacement personnel when there are not enough qualified SLPs to meet the demand.
8. The number of North Carolina public school children in need of speech-language therapy whose therapy would have been delayed if it were not for this program is undoubtedly in the thousands. This is the ultimate measure of the success of this distance education program.

Architecture of an E-Learning System with Embedded Authoring Support

baudry@informatik.uni-hamburg.de

Abstract: In this paper we introduce an architecture for an e-learning system with an embedded authoring system. Based on the metaphor of a construction kit, this approach offers a general solution for specific content creation and publication. The learning resources are IMS "Content Packages" with a special structure to separate content and presentation. We call these packages "Template Content Objects" (TCO). They contain a template coded in XML and additional files for multimedia learning objects. TCOs are similar to the SCORM "Sharable Content Objects" (SCO) and can be simply translated to them. The authoring system consists of different authoring tools that handle TCOs. Every task in the process of learning object creation is done by experts which we modeled with the help of roles. The architecture is a result of the math-kit project, a web based e-learning system that provides instructors and students with multimedia support for central topics in undergraduate mathematics.

Introduction

Our goal is the development of a multimedia construction kit, called „math-kit", that supports the learning and teaching of mathematical and technical content (Mathkit 2002, Unger 2002). Hence, the math-kit project provides a mechanism to find and combine learning objects to compose them to complete learning units and online courses. Students will be able to use math-kit to work through online courses to refresh their knowledge or to use the tools for further exploration of course material. In the same way the students use courses, instructors could apply parts of the courses to their lectures to make them more accesible to students.

Math-kit is a joint project, which is being developed at the German universities of Hamburg, Bayreuth, Hagen and Paderborn[1]. They combine their technical and didactic skills to produce mathematical and technical learning units for interdisciplinary use in higher education.

In a joint project, the creation of uniform learning content is very difficult to achieve. Often, different developers produce learning objects which are based on varying description languages such as HTML or PDF. The software market provides several tools for content creation, for instance, Microsoft Word, Adobe Acrobat, Adobe Framemaker or Macromedia Dreamweaver. Each of these programs provides special functionalities for specific problems but has weaknesses in other tasks. Also, defining rules for the style and layout of content is insufficient because the process of individual combination and the reuse of learning material in other contexts is not possible. For this purpose the architecture of math-kit uses the construction kit metaphor (Bungenstock 2002) that we have developed as a solution for this problem.

Briefly, this metaphor helps to plan a software system that supports both students and instructors in improving their work. To understand this metaphor, think of a LEGO construction kit with all contained bricks. The unique design of the bricks allows a multitude of stable models. In the math-kit context the learning objects are the bricks, which can be combined to individual courses. To define such a brick in a e-

learning system, we provide the TCO approach that uses the *Extensible Markup Language (XML)* (XML 2002) to separate content and layout of learning objects.

Template Content Object

Before we describe the architecture for the math-kit project in detail, a deeper understanding of our special template mechanism is required. Our *Template Content Object (TCO)* is inspired by the *Sharable Content Object (SCO)* of the SCORM standard (ADL 2002) which has a strong influence on our design. Briefly, a SCO represents a collection of different files, called assets, and is the atomic learning resource for a *Learning Management System (LMS)*. One SCO is intended as a small and independent unit to be reused in different learning contexts. All learning resources and additional metadata describing the SCO can be bundled by a special *Content Package* mechanism based on the standard of the IMS (IMS 2002). SCORM offers two content packaging application profiles that describe how IMS content packaging is used. Both *resource packages* and *content aggregation packages* use a *manifest* for the internal description and the same file encoding like zip compression. However, significant differences exist between them. A resource package contains only assets with no relations or order and is therefore the SCO. The content aggregation package consists of SCOs or other content aggregations and offers higher structuring. Hence, higher-level structures like lessons, sections and chapters, as well as complete courses, can be built in the same way. Figure 1 illustrates the levels of content packaging. The arrows show the inclusion relation.

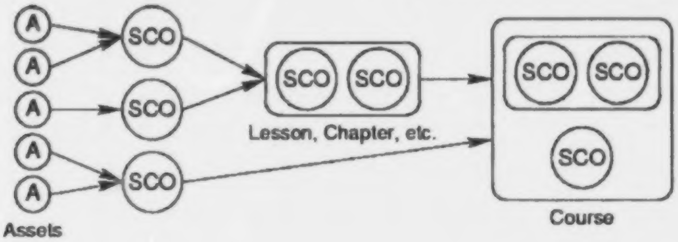

Figure 1: Recursive content packaging

In this simplified example, a course is a content aggregation package containing another content aggregation package and a resource package/SCO. The recursive definition of content aggregations allows any structure depth for learning content desired.

For assessment of learners, SCORM defines a simple protocol for comunication between SCO and LMS. At runtime, the SCO obtains the API adapter of the hosting LMS for interchanging data about the learner's behaviour.

The SCO approach meets the demands for content interchange and execution but lacks some important features for content creation. As already mentioned, the separation of content and view is one of the essential goals of math-kit. Therefore, the *Extensible Markup Langugage (XML)* and the *Extensible Stylesheet Language Translations (XSLT)* (XSLT 2002) are used. A TCO has the same structure as a SCO with the exception of one special asset: a template written in XML. In the case of math-kit, the template describes the texts, mathematical definitions and formulas in a well-defined fashion. Templates can be used for every kind of content but they depend on a special XML encoding. The further assets in the TCO are required only for the later translation of the template into a readable output format, like HTML or PDF. To make the conversion clear, figure 2 shows an example with a TCO containing two images and one animation. The TCO is translated into two different SCOs whereby the varying number of files in the SCOs is caused by technical differences. The PDF file format allows the integration of images but HTML contains only references to other resources.

BEST COPY AVAILABLE

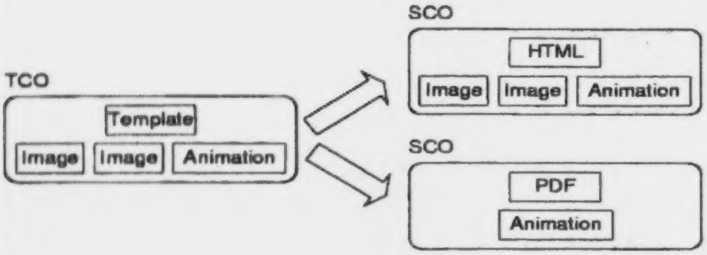

Figure 2: A TCO converted into two different SCOs

The translation process is controlled by different XSLT files which are used to convert XML into any hierarchical file format. Thus, the individual appearances of one TCO can be realized with only one translation technique. For instance, if you need to show the emblem of your company, school or university in the upper right-hand corner using particular colors, you only have to modify the XSLT files and not the template. This means that a created TCO never has to be changed for visual modification.

The Roles

We introduce roles to model the different views of our e-learning system. It is important to comprehend that one person can appear in several roles. The roles help us to model the static and dynamic behavior of our system with use cases and sequential diagrams (Bergner 1998). This allows us to have a strict and controllable development process.

Six different roles can be defined with math-kit: instructor, student, composer, learning object developer, publisher, and administrator. The *instructor* uses single blocks or complete courses to extend his own lectures or to create new ones. Important operations for this role are searching and archiving. The *student* role needs similar operations but for another purpose. Individuals in this role want to learn and can explore the entire database to use learning objects and courses of interest. These two roles don't depend directly on the construction kit metaphor because they work with math-kit through a LMS. Nevertheless, the construction kit is the foundation of the created content.

The composer uses math-kit to combine existing learning objects to make complete courses. Useful operations for this role include searching for learning objects, combining, previewing and perhaps editing. This role creates and edits the content package. In relation to the construction kit metaphor, the composer defines the construction plan. The *learning object developer* designs and implements new learning objects. This role consists of collecting and assembling the different assets like images, texts, and animations to SCOs. In view of the metaphor, the learning object developer creates several bricks. In context of math-kit, the learning content is coded in XML with a structure for mathematics. This XML code has to be translated into a readable format by the role *publisher*. Hence, the main operations of the publisher are the definition or choosing of particular styles and the compilation of the source document to a destination format. The last role, *administrator*, installs basic packages and software for the construction-kit. The main task of this role is to help all the other roles with technical problems. Maintenance, consulting and user administration are the important operations.

A little example should make the relations among the roles clear: Consider a professor who wants to extend an existing lecture in computer engineering with a multimedia course. First of all, the professor is in the role of the composer. Math-kit offers a wide range of content and most of the required themes ideally should be available. If some content is missing or has to be adapted the professor slips into the role of the learning object developer. For instance, the learning object developer is able to integrate the mathematical content of a colleague, which is not stored in math-kit. Figure 3 shows the role of the composer creating a course for computer engineering.

Figure 3: The roles that interact with the construction kit

After the course is completed, another person, such as a scientific assistant, takes on the role of the publisher. He can adjust the university emblem or any other style-related features like font, background color or page size. The product, a viewable document in a preferred format, is used by the professor, in the role of instructor, in his lecture to illustrate complex themes with animations. If students do not understand everything during the lecture they can read the complete course online at home. If a student needs more detailed information, for example about complex numbers, math-kit offers the whole database of content. Furthermore, the student is able to work through special exploration units which are provided by the professor as well.

The role of the administrator doesn't appear in this example because this role exists only to support the other roles.

Architecture

To understand the realisation of the construction kit it is necessary to have a look at its architecture. Usually, students use online courses through *Learning Management Systems (LMS)* such as LON-CAPA or Blackboard (LONCAPA 2002, BLACKBOARD 2002). A LMS provides different categories, for instance communicating to other students, sending solutions of exercises to lecturers, work through courses or use of multiple choice tests for check progress. The courses can be created with the help of authoring tools, for instance macromedia's authorware application. Unfortunately, these tools can only be used for universal content creation. They provide solutions for quizzes or give the author the possibility to adjust predefined design properties. In the math-kit project we need a special mechanism to define individual learning content. On the one hand, learning objects should be combined and transformed to individual courses. Thus, an authoring tool must provide the possibility to define learning objects without any style definition. On the other hand, different output formats should be provided as well. To meet this demand, the need of an abstract mechanism to define equations is required.

BEST COPY AVAILABLE

Based on these facts, we used an arbitrary LMS to provide the content of math-kit. This enables students and instructor to use their favored webbrowser to work through the courses or to select a special course block for presentation in lecture. However, the process of content creation must be supported by special tools in order to meet our requirements. According to the role concept, the learning object developer, the composer and the publisher are experts in content creation and each of them has his or her own tool. Related to our construction kit approach, these tools work with a server that stores courses and TCOs as bricks.

Thus, the *Constuction Kit Server* (CKS) is an important extension of existing LMS for individual content creation. Figure 4 shows the CKS and its tools.

Figure 4: The architecture of the construction kit

The tools are split up into two groups: one for distribution and the other for development. The development tools are used to produce content packages that will be distributed to instructors and students through the LMS.

The tool for the *learning object developer* creates new TCOs that can be stored into the CKS. It enables the developer to create or modify templates easily by integrating new assets, for instance, images, texts or applets. As already mentioned, the TCOs usually content packages that consist of one XML-file with several referenced assets. The developer works on a copy of the original TCO file which is stored on the construction kit server. The client works on his or her own copy of the TCO. Thus, when a TCO is saved on the CKS the copy is merged with the original file. This is achieved by the use of CVS, a system to handle concurrent work.

For the *composer* role a separate authoring tool is available. This tool helps the process of combining TCOs to create the so called *content aggregation packages (CP)* (courses). Therefore a manifest file that contains the structure of the course has to be created. In relation to the construction-kit metaphor

BEST COPY AVAILABLE

the manifest is the construction plan. In Addition, the composer is able to search for existing TCOs by keywords based on the *case based reasoning (CBR)* (Watson 1997).

Another tool is available for the publisher for transforming content packages into courses that can be stored into different LMSs. With the help of this authoring tool, an individual design and layout can be defined. The CKS uses a stylesheet that is generated by the tool of the *publisher* which can transform a content package into a special output format, such as HTML or PDF. Using XSLT to transform source XML-files, the publisher has the option of choosing a predefined layout, modifying an existing layout or defining a new layout.

The consumer of the learning content doesn't pay attention to the CKS. They only have to access a LMS to work through courses or to use single learning objects for lectures.

Realisation

The implementation of the construction kit is influenced by the previously mentioned SCORM standard. All specifications in SCORM offer XML bindings so that a XML parser is needed. Because of platform independence, Java is our programming language of choice. Standard interfaces for XML processing in Java exist which are supported by many available parsers. For confidence we use JDOM (JDOM 2002), a simple XML document representation in Java with its own API that is similar to the W3C DOM (DOM 2002) but offers more comfort. With these tools it is quite simple to read, edit and write the manifest of a content package.

The authoring tool for the learning object developer allows the creation and modification of TCOs. This requires the handling of resource packages containing a template, assets and a manifest. To facilitate the work with TCOs, the direct manipulaton of assets should be provided. This gives the opportunity for a rapid implementation process controlled by one tool. The connection between the contained files and the tools must be realized via the *Multipurpose Internet Mail Extensions (MIME)* (MIME 2002). This specification defines among other things media types and subtypes to classify data. The application can determine the media type of a particular file in several ways, e.g. by the file extension or an analysis of the file beginning. Furthermore, every media type should be combined with an action, i.e. create, edit, or show.

A combination of media type and action is adhered to a Java component, called *JavaBean*, or an external application like a PDF viewer. Sun offers the *Java-Bean Activation Framework (JAF)* (Calder 1999) which supports the development of MIME media type driven applications. For better integration of self implemented or foreign JavaBeans a mechanism is required that allows dynamic and flexible adaption to personal needs. Java is a strong typed language and therefore programs have to be recompiled after every change. To get an acceptable solution, we recommend a scripting language as a bridge between the construction kit and the Java-Beans respectively external applications. An interpreter, called Jython, of the object-oriented scripting language, Python, exists for Java and is easy to integrate in applications. This combination of Java and Python provides all the benefits we want to offer with our appliation.

The composer role needs content packaging as well as search functionalities. Different TCOs have to be combined to higher structures, in detail content aggregation packages. Therefore, the right learning resources have to be offered by the authoring tool. For the realization of the case-based-reasoning searching, special data records have to be stored. The adequate solution to store these records is a relational database system. With the JDBC API (DOM 2002) of Java, a SQL driven implemetation could be done indepentendly of the concrete database system.

The publisher role needs support for the creation of styles but for most authors it is not reasonable to code XSLT files. Hence, the authoring tool offers an abstract view of the translation process. Every tag appearing in a template needs its own translation rule. To automate such a style process, a meta description for the templates is necessary. With this information, the authoring tool can support the publisher.

For the translation into readable output format, different rules and perhaps special pre- or post-processing components are required. Consider PDF as the desired output format. One solution could be a direct transformation into this format but this would result a huge programing effort. A more simple way to get PDF is the usage of *LaTeX* (Lamport, 1998). In this case, the template is translated into LaTeX code by XSLT and then into PDF by the post processor calling the LaTeX program.

Conclusion

We presented the architecture of an e-learning system that is based on the construction kit metaphor. With such a system, courses can be created by the usage of already existing learning resources based on our TCO approach. This approach makes it possible to adapt learning objects to different courses independent of their format and style. The architecture was developed in relation to the role concept. The definition of the roles working with the construction kit helps us to develop an architecture of an authoring system that can be used by students as well as professors to improve their work.

The universities of Hamburg, Hagen and Paderborn effectually use the construction kit to produce their courses (Padberg 2002) in the field of computer engineering as well as mechanical engineering.

Abstract

The Education Network of Ontario (ENO) is a telecommunications corporation creating an access and applications network for and by Ontario's 130,000-member education community. When educators register with ENO, they receive full industry-standard Internet and Intranet services in English and French. ENO/REO works from school or home. Statistics such as 100000 teacher members, over 23000 logins a day, 25000000 minutes a month of online time, and over 100000 mail or news messages per day are commonplace. Self-nominating teachers lead projects that deal with content creation, classroom projects and technology exploration. Results are as varied as a database of parent letters to go with report cards, solutions to keep small children exercised and content in ultra-cold winter months, an Internet radio station and investigation of video and voice technologies as well as pedagogical practices to support professional development.

We train teachers who now understand the need for, and use of, a sophisticated variety of applications and content to support and motivate students in our online environment. The result of this support is a classroom project model that is firmly based in curriculum but created in a way that the students and teachers use access to the Internet and other technologies to enhance learning of subject matter and processes, and not the technology itself.

The ENO project model is supported by an automated application so teachers need not become involved in web functions and software operations themselves. They do not need to understand web site creation or even negotiate web hosting with their school or District School Board. In this way they work from the outset with the skills and experience they already have and they add knowledge of online processes and course management only as they need them in practice. Many project leaders graduate from this initial template to major web site creation. Because we are our own Internet and Intranet Applications Service Provider, we have enabled teachers to create and use a continuously evolving 'bootstrap' model to support diverse, creative activities – projects, group work, lessons and student-to-student exchanges at every level of instruction.

1. Introduction/Context

The initial stage of the Education Network of Ontario (ENO) was a UNIX-based, cross-platform, TCP/IP distributed network which provided bilingual (English and French) electronic mail, moderated conferencing (facilitated newsgroups), and database and Internet access across Ontario. It consisted of a bulletin board system with just eighteen members in 1993 and has grown to register more than 100,000 teachers, administrators, trustees and education faculty. This now constitutes nearly the complete K-12 education personnel of the province.

The organization, a public sector Internet and Intranet Applications Service Provider (the second largest in the province), has moved from a project for the Ontario Government to become an independent not-for-profit corporation selling services to various levels of government and private and public sector organizations in Canada and abroad.

The project retains dial access from any educator's home or school location in Ontario as well as a full set of mail and newsgroup services. However, to assist teachers with implementation and to resolve issues of the blocking of traditional newsgroups, ENO is structured to enable browser-based moderated Intranet newsgroups and model classroom projects with interactive web creation scaled to accommodate hundreds of thousands of teachers and students as they develop creative, commercial level content. A bilingual call centre supports all of the members and a web site supplies automated tools for registration and classroom project creation.

2. Statistical Notes

Quantitative analysis tells us that our membership of 100,000 educators uses the dial access on average 20000 times a day. Statistics show total online time of nearly 20,000,000 minutes a month from the dial clients. This is in addition to access from school or office LANs and other service providers. Our servers handle as many as 100,000 messages a day. Some of our classroom activities sites register 30,000 hits a day during peak activity. Our records show that teachers have a sustained interest in the Internet and ENO resources, with 80% of the connect time registered after school and throughout the night. Any one of the hundreds of teachers involved in an 'ENO' classroom project, either in creation or participation, is using home or library access after-school hours because of the classroom pressures of their days.

3. Teachers' Practices

Our anecdotal analysis and day-to-day experiences tell us a great deal about how educators use this suite of services. One focus of the teachers continues to be moderated conferences/discussion groups that they open to solve such endemic concerns as 'local' versus 'standardized' evaluation, reporting to parents, community work/learn programs, and general subject-based or level-based curriculum issues such as primary school or science teaching. Whenever a new provincial license for software is purchased, a discussion group is opened in which the technical support team from the vendor can discuss issues of use and technical implementation.

Smaller groups of teachers voluntarily initiate a series of professional activities such as writing primary school curriculum units based on concepts such as two dimensions – measurement, journaling, drawing, and electronic and snail mail. This arose from a successful example, the web-based project devoted to showing young students how to conceptualize two dimensions with a central fictional character called 'Flat Stanley'. After the provincial collaboration, teachers mount and maintain the curriculum units on the ENO/Flat Stanley web site. This project is now international with thousands of schools and hundreds of thousands of students participating. Teachers in other jurisdictions are beginning to write curriculum modules and asking for them to be added to the site.

4. Classroom Projects

One of our largest projects involves over 100 schools and 4000 students across Canada. The Canadian National Marsville Program is a complete online and face-to-face environment. It is a content, activities and teacher professional development project based on the concept of intermediate-level students in a simulation of creating a living environment for themselves as pioneer astronauts and settlers of Mars. Students work through four months of content and activities to ensure their survival as Mars settlers. They upload team mission patches and then their air, water, energy, communications and food supply system drawings to their team's web pages. They and their teachers use the web to access content, activities and mentors' comments from companies such as Spar Aerospace or Macdonald Detweiler and the Canadian Space Agency. Both students and teachers use their personal Intranet accounts to use email and discussion groups to communicate with one another as they improve their devices for space exploration and prepare for the final 'link-up' day. Using technology applications such as newsgroups for sharing and interactive

BEST COPY AVAILABLE

web authoring prior to the face-to-face event enhances classroom learning. It is not an add-on or a distracter to normal classroom routines.

5. Project Model

The pedagogical model that is the basis for Canadian National Marsville is based in many years of practice, is demonstrably sound, and produces students who are motivated to learn. We have both system-derived and anecdotal evidence of increased achievement. We use this model of sophisticated technology integration, as well as a wealth of offline activities into problem solving simulations, for most of our funded classroom activities.

The following are the parts of the model with explanatory notes. It should be mentioned that the model is not linear and that teachers and curriculum specialists begin in a number of different ways and places in the model. We do ask that ENO project leaders, before they commence, consider all of the parts of the model, even if some segments are eventually deemed non-essential. To aid in understanding, I will use a consistent environmental problem example.

Problem

In this phase, the teacher determines the area of concentration of study. If the student group is at the elementary level, this will naturally be an integration of many disciplines. If the secondary curriculum area is determined to be science, the problem might be the issue of the level of pollution of the local river and feeder water. In all cases, it is preferable if there is more than one teacher and more than one discipline strength involved in the project. The students should pick the final problem or it should be incredibly interesting to students because it is a problem that is local and newsworthy and it starts with their knowledge of, and interest in, the issues of the project.

Scenario

The teachers then create a simulation or scenario into which the students can place themselves as they seek first information and then solutions. In the river pollution example, the scenario would involve a condition of the local river, a series of industries involved in proper and improper waste management, for instance, and the governmental agencies responsible for the river's water quality. The students could form the waste management and biological/chemical company consulted by local industries to study the issue. Another group of students could be the governmental agencies responsible for the river and local water quality. A group of four to six teachers, each with a different area of expertise and a shared commitment of time and resources for the project undertakes the development of activities that appeal to a large number of students since they will blend science with the study of legal regulations and the government as these relate to water. This embeds the knowledge of ground water and its properties and occurrence in the world of governance and political science. Because of the way it is framed from the teachers' initial plan, students become informed, responsible citizens mobilized to protect the environment, even as they come to understand the scientific principles which underlie their insights and conclusions

Team Roles

The scenario will determine the number and types of roles that can be given to students. In the river pollution example, the company would need a series of officers whose different skill sets might be mathematics (Chief Financial Officer), science (chemists, zoologists and botanists investigating the quality of the water and the species living in it), or media studies (creating the documents and multi-media objects used to create the case for the solutions). Students in history, business, or citizenship classes take on the roles for governing officials to study science from the point of view of regulations, their objectives, and their timing.

BEST COPY AVAILABLE

The more realistic and diverse the roles, the more students can divide the activities to concentrate on specific content. This increases motivation and encourages students to remain focused on solutions. It also allows them to study the core science in the context of their personal strengths. The more completely the students incorporate their personal roles, the more they will act professionally when they consult people in the community who have responsibility for these duties.

Clarification of the Problem and Critical Thinking

The students are presented with the scenario and assume their roles. They begin to clarify the problem and determine the area in which their characters will focus their efforts. They must state the problem clearly, assume the tasks of their roles, and determine the focus for their solutions. This is an important step for the students and is the best indication of how well they understand the problem. The teacher's main task consists in nudging the students to a good understanding of the issues in the problem. In the river scenario, the focus could be organometallic contaminants from local industries and their effects on flora and fauna in the river. A second group could focus on contaminants of drinking water and the ways that they are eliminated. Work needs to be accomplished by any one group in a sufficiently speedy way to keep the project in perspective and on schedule in the curriculum year.

Content Acquisition

The students in their roles now begin to assemble content and create solutions. Sources of information may be the more traditional ones of newspapers, books, and videos or even films. However, these students benefit by being able to access content on the Internet and determine its worth, validity, and timeliness. There are often groups in the community who can act as online mentors who are identified by teachers and who can be accessed by email or who participate in the discussion groups as the students gather their information. Student interviews with members of the community are worthwhile since much needs to be mastered and organized before the students leave the school to interview off-site.

The teacher can assist with the accuracy and completeness of the content by directing members to a wide set of possible sources. At this point, traditional classroom lessons on core content are an asset. They may be face-to-face or online with checks that students have mastered the core ideas.

Activities

As the students gather their content, they begin to assemble and integrate it into solutions based on their new knowledge. It is important that they do many offline activities in natural, role-based groups so that the discrete content they have gathered can be taught, debated and authenticated by the whole group. Activities should be stepped so that students are not overwhelmed. Solutions should culminate in substantial products that are well-documented and complete. For instance, students could create a public policy paper calling for new chemical limits, with supporting documentation from other jurisdictions and their experiments with their local water sources and supplies. They might create a digital video to show members of government or the community the present case with a model and evidence for desirable change. The product depends on the context and capacity of the classroom.

Solution/Assessment

As the students work on their activities, they will create products which need attention from the teacher and mentors. If the students have not found sufficient content or have been sloppy in collecting and presenting evidence, the solutions posited may be superficial or even wrong. Teacher intervention can turn students to redress this and the solutions can go through iteration to ensure that students work much as developers and writers working in the 'real world'. In most cases, students enjoy the opportunity to learn more and their improving solutions become a source of pride. The students finish when they and the teacher are satisfied, but motivation remains high where initial goals and schedules are followed.

Exhibition

This model for learning benefits from an opportunity to exhibit solutions. Face-to-face events are optimal if much time has been spent using technology in groups separated by distance. A final event like an exhibit, a presentation to the local municipal council or even a synchronous event among schools supported by videoconferencing will enable students to polish products for a deadline and for someone else than their school and teachers. In some cases, an exhibition may be the only way to make students complete and move to other studies.

6. Implementation Notes

Teachers can approach this model in a variety of ways. They can start with a scenario that is exciting to students and work backwards to make the curriculum links. This will often happen to a certain extent because good teachers will think of various other parts of their curriculum that they are accomplishing in these problems such as communication, co-operative work, career study, or even the use of technology in their discipline.

Teachers often start with a relatively rudimentary scenario but as they begin to trust the focus and variety of approaches that the roles afford students, they invest more time and energy in the scenario or simulation description. Student motivation is directly proportional to the excitement of the scenario problem.

All sections, but particularly the core content and activities, are profitably produced on the web since the project web site will give students the framework for their work. Many teachers working on one project can make a substantial site with activities which will encourage other teachers to join them, use the project, and suggest improvements. A number of teachers will also help in establishing a solid foundation for student evaluation. Only if the curriculum objectives are apparent and the evaluation methods authentic will a critical mass of teachers in a jurisdiction adopt the project and make it worth the effort that has been expended by the first core teachers. Once this happens, the effort to enhance the site is minimal and the returns great.

The project model has been incorporated into a web application that allows teachers interested in initiating a project to create a web site which describes their problem, establishes their team, and establishes their 'lessons'. External teachers can request to join a team and then enhance the site with their additions. Projects that are very creative and attractive often grow out of this template environment to full web production supported at a provincial or national level.

In all of this activity, ENO is in varying degree enabling personal, small group and province- and nation-wide professional development. As such, some of our activities have been researched and monitored or even funded by research grants. We have yet to induce research into this model but many teachers in Ontario, Canada, and even around the world have adopted it.

6. Partnerships and Sustainability

Our work with the Ontario education community has burgeoned to other Ontario and Canadian government ministries and jurisdictions. This gives us economy of scale and allows us to move services through a developing spectrum not dependent on individual contracts.

We are working with Brazil to support secondary reform to integrated disciplines and critical thinking through technology. This involves four projects in at least seven states with nearly one hundred schools and hundreds of teachers over the next two years.

7. Summary

All of this experimentation, integration, and implementation create a healthy and knowledgeable corporation able to develop and offer vertically integrated services to communities, professional groups and government ministries and agencies. We use the economies of numerous parallel contracts to continually improve our service and applications offerings. As we embark on our international activities, we invite participation and partnership.

The Changing Role of Instructors in Distance Education: Impact on Tool Support

Abstract: At the university of Hagen a lot of experience exists in performing web-based teaching and in implementing tools supporting e-learning. To share this knowledge, (inexperienced) instructors more and more ask for tool-based assistance in designing and administrating e-learning courses. Considering experience from other universities it becomes obvious, that there is in general a lack of a broad system support of tasks to be fulfilled while performing e-learning. Within this paper we propose an adaptable course assistant which provides the required tool support. It helps in selecting and utilizing Internet and web technology, respectively. The knowledge of how to run a virtual course is modeled by means of course templates, which may be adopted to special needs. Before introducing the assistant we will discuss the changing role of instructors in distance education and its impact on the requirements of tool support with respect to designing and administrating a course.

Introduction

At the university of distance education (FernUniversität) Hagen, Germany, a lot of experience exists in performing web-based teaching as well as in implementing tools supporting e-learning (e.g. Buhrmann et al. 1997). In the beginning the main objective of the projects started to introduce e-learning was to remove the severest restrictions of traditional distance teaching. The decision to perform web-based teaching and thus to use the tools and platforms developed was up to the instructors of the individual courses.

Caused by the fundamental decision to "bring the whole university on the net" (Hoyer 2001) the different systems were integrated into one single platform, the *Virtual University*[1],[2], to be used by all instructors for online teaching. Thus, in general, the role of instructors in distance education is changing imposing additional and new tasks on them. They have, for example, to develop web-pages, moderate newsgroups, or administrate cooperative learning environments. Besides such tasks resulting from using the Internet-based tools and services, instructors have to redesign their teaching courses and to find new ways of distance teaching. Altogether, the predominant question, not only of inexperienced instructors, is "How to utilize Internet technology to enhance web- based teaching and learning?" This implies aspects of didactics as well as of the technique to be used.

At the university of Hagen several workshops are organized periodically within which instructors share their knowledge ("teach the teacher"). However, organizing as well as participating in such events is often claimed to be too time consuming. Furthermore, it doesn't help if an instructor needs ad-hoc clues for designing his online course. Instructors of the university more and more ask for tool-based assistance in designing and administrating e-learning courses. Considering experience from other universities it becomes obvious, that there is in general a lack of a broad system support of tasks to be fulfilled while performing e-learning (e.g. Klobas & Renzi 2000, Tielmans & Collis 1999).

Within this paper we propose an *adaptable course assistant* which provides the required tool support. It helps in selecting and utilizing Internet and web technology, respectively. The knowledge of how to run a virtual course is modeled by means of course templates, which may be adopted to special needs. Before introducing the assistant we will discuss the changing role of instructors in distance education and its impact on the requirements of tool support with respect to designing and administrating a course.

---

[1] https://vu.fernuni-hagen.de

[2] This system is currently being improved and extended by the developer group of the University Computer Centre (URZ) as well as by research groups of different departments.

From traditional distance learning to web-based learning

Traditionally, the university of Hagen delivers its learning material (textbooks and workbooks) in print. The material for a course is partitioned into units to be sent to the students sequentially. Each unit is designed to be worked out within a time period of two weeks. Communication takes place by means of traditional media like telephone and physical mails.

In a few cases the students have to be physically present at the university. Typical examples are hands-on trainings performed in a lab located at the university or oral examinations. This conventional mode of distance teaching and learning is afflicted with different kinds of problems, most of which can be avoided by using Internet technology, and tools and services based on it. In 1996 the university of Hagen started several projects towards becoming a virtual university. Within these projects interactive and multimedia learning material as well as tools and platforms supporting e-learning were developed. The latter are now integrated into a coherent platform constituting the teaching and learning environment of the whole university. In the beginning the main objective was to remove the severest restrictions of traditional distance teaching:

In time feedback. From the students' view, as all learning material was delivered by physical mail, the time delay between sending their homework and receiving feedback (e.g. corrections and comments) were too large. Often students got remarks on their exercises several weeks later when they were already working on other topics of their material. From the didactical prospect this disadvantage was one factor of slowing down the learning process. Tools incorporating Internet technology, e.g. WebAssign (Brunsmann et al. 1999) which supports submitting and receiving electronic assignments, enable students to receive feedback in time.

Being up-to-date. Because of the typographical process instructors had to hand over the complete learning material of each course to the print office six months before it started. Using web-based delivery facilities enables ad hoc modifications, e.g. to introduce latest research results into the course material.

Enhanced communication. At the traditional university of Hagen the communication between instructors and students was usually reduced to information letters (regularly sent to the students to announce course information) and telephone calls. Using synchronous and asynchronous communication services of the Internet enables in time information and tutoring as well as building communities between students.

Virtual presence. Students participating in face-to-face seminars or hands-on experience had to be physically present at the labs of the university. These types of courses are often criticized as being too expensive and time consuming as students have to travel from far away. The web-based forms of these course types (*Virtual Seminar* and *Virtual Practical*) enable the students to meet in virtual rooms (Berkel & Mittrach 1997), to perform laboratory experiments by remote control or by means of simulation and visualization within a virtual environment (Bischoff & Röhrig 2001).

The Changing Role of Instructors

As shown in the above examples introducing web-based teaching enables instructors to enhance learning and teaching for the benefits of the students. On the other side, the role of instructors changes:

- from textbook author to author of interactive and multimedia learning material,
- from text provider to tutor interacting with students by means of the new communication facilities like e-mail, newsgroup, and chat,
- becoming a group member slipping into different roles within computer supported collaborative learning environments,
- being a user of the new media utilizing Internet techniques and tools,
- becoming a course designer defining different e-course types, e.g. Virtual Seminars or Virtual Practical,
- becoming a course administrator, e.g. administrating the course web-site.

Years of experience show that the acceptance to adopt the new role varies between instructors. It becomes obvious that it is highly influenced by the fact whether the decision to perform web-based teaching is driven *externally* or *internally*.

The dominant external factor is given by the decision of the institution to bring the whole university on the net, i.e. to launch a virtual university (Hoyer 2001, Krämer 2000). In addition, and this holds true for distance universities in general as well as for traditional universities, instructors have to be online. They are expected to provide an Internet presentation showing, e.g., their research topics and teaching activities. Furthermore, students more and more ask for web-based learning materials.

If external aspects constitute the main factor for introducing web-based teaching acceptance is generally low. In particular, the following aspects were identified as problems:

- How to use Internet technology and services as well as tools based on it? (aspects of the technology to be used)
- How to perform web-based teaching? (aspects of didactics)
- Will the Virtual University prescribe how to teach? (independence of teaching)

Although web-based learning and teaching is in its infancy and still evolving, distance education can benefit from it in many respects. Hence, most of the instructors are motivated to investigate ways of e-learning within their field of research and applying it in practice. In this case changing the role of instructors is driven internally, i.e. motivated by themselves searching for answers to the questions mentioned above.

The division in externally given decisions and internally driven motivation is not as strict as it may sound above. It shows only two extremes somewhere between which the instructors are located. In addition to these factors the acceptance of the new role is influenced by the knowledge and experience in computer and Internet technology of the individual instructor. In other words, it depends on existing tools enabling e-learning. In the following we will focus on tool support with respects to course design and administration, as other aspects are often discussed elsewhere.

The Role of Course Designer and Course Administrator

How can the Internet be utilized to enhance web-based teaching and learning? There are a lot of decisions to be made with respect to the structure of virtual courses, their organization (e.g. announcements of examination, providing course web pages) and the use of existing tools and Internet services (e.g. the possibility to use an Interned-based exercise system or chats).

Forms of teaching	**Aspects of didactics**	**Tools, Services**
Virtual Lecture (basic version)	S: self-study of learning material, solving exercises; ... IS: communication (tutoring); ...	text processing system, web-editors, authoring systems E-Mail
Virtual Lecture	S: self-study of course material, participation in the Internet-based exercise system, participation in discussions, ... IS: communication (tutoring); ISS: communication (exchange); ...	text processing system, web-editors, authoring systems, newsgroups; E-Mail, chat; ...
Virtual Seminar	S: self-study of course material, elaboration and presentation of a topic, team-work, ... ISS: communication (participation in discussions, exchange of contributions), ...	text processing system, web-editors, authoring systems, up-load-areas, newsgroups; E-Mail, chat; ...
...	...	...
abbreviations: S: Student, I: Instructor, IS: Instructor and Student, ISS: Instructor and Students		

Table 1: Rough classification of existing kinds of learning activities

At a university there are different kinds of teaching events like "lectures" (i.e. courses within which content is delivered analogical to traditional lectures), seminars, exercises, and practical trainings. For each of them different forms of performing them "virtually", i.e. based on Web and Internet technology, are elaborated. Table 1 exemplifies a rough classification of *Virtual Lecture* and *Virtual Seminar*, showing didactical aspects and the tools and services typically used within these course types. The example shows that different concepts of teaching forms and specifications are realized. In the basic form of a Virtual Lecture, for example, the instructor and the student communicate by E-Mail. In its version described in the next row newsgroup and chat are used in addition to support group discussions of students. Usually this communication tools are also used while running a virtual seminar, within which additional services are utilized, e.g. ftp as entrance for an up-load range for the exchange of elaborations.

In particular, instructors who are inexperienced with e-learning like to access existing knowledge. Therefore, at the university of Hagen several workshops are organized within which instructors have the chance to share their knowledge ("teach the teacher"). However, organizing as well as participating in such events is often claimed to be too time consuming. Furthermore, it does not help if an instructor needs ad-hoc information for designing his online course.

Even if an instructor knows how to design a virtual course the tasks related with its administration often cause significant problems and effort. The influence of this additional problem can be discussed in terms of *technical aspects* and *degree of support*. Many instructors have problems to handle the platform (often the effect of the "users don't read manuals" phenomenon) as well as Internet services like videoconferencing or chat-rooms. Even if the services are well known their handling appears confusing due to the different user interfaces providing access to them. Inexperienced users require a simple integration of Internet services thus "hiding" the underlying techniques. Experienced users ask for an open system allowing easy integration of additional services and tools. Furthermore, this group of instructors wants to get rid of tasks dealing with technical aspects, for example, administrating a server or setting up a chat room or newsgroup.

Tool Support: Adaptable Course Assistant

Altogether, besides assistants in developing learning materials the instructors require functionalities for administrating and managing courses. Considering experience from other universities it becomes obvious, that there exists in general a lack of a broad system support regarding different processes, which takes into account organizational as well as teaching tasks to be fulfilled while performing e-learning (e.g. Klobas & Renzi 2000, Tielmans & Collis 1999). Thus appropriate system functionalities have to be implemented with regard to

- aspects of didactics (e.g. showing the instructors how to utilize Internet technology in online courses),
- technology to be used (e.g. free the users from pure technical aspects as far as possible), and
- organizational aspects of a course (i.e. of the university as these are part of running a course, e.g. exchanging data with the examination office).

To provide such system support we are currently developing an adaptable course assistant[3] supporting instructors in selecting and using web technology while they are planning and running their courses. The basic concepts are:

Course Templates. Based on the instructors experience each course template describes a possible way (as a small workflow) of running a type of course, e.g. a web-based seminar, lecture, or practical course. It shows how and when different technologies of the web may be utilized while running a course. Thus, the course templates are reflecting the knowledge about the appropriate technology to be selected in the context of a specific type of course.

Configurable Building Blocks. A template consists of different building blocks. Each one groups functionalities provided by the platform Virtual University or offers special web-services, e.g. functionalities for using a chat room. Most of the building blocks can be configured according to special needs of an individual course. The chat building block, for example, provides parameters for specifying the date and time within which the chat should be available. As an example, the left frame within the window in figure 1 shows a template of the essential version for content teaching courses (named *Basisschablone*, Basic Template in English). The structure of the building blocks constituting a template are visualized by means of a hierarchical tree notation.

---

[3] in German: ALVA – Adaptierbarer LehrVeranstaltungsAssistent; the project is funded by the Federal Minister of Research and Technology

Adaptability. Most of the instructors have their own ideas about how to realize web-based teaching. For example, an upload-area or chat room is not used by all of them within a virtual seminar. In addition, even a single instructor changes the way of handling a given course from time to time. Hence, support is required not only for different types of courses but also for different ways of processing a special kind of course. For this purpose a course template is adaptable, which is realized by means for removing and inserting building blocks. The editor supporting adaptation is depicted in figure 2 (a), which shows a modified version of the basic template containing additional building blocks with respect to the template shown in figure 1. The working area comprises a list of building blocks which are provided by the assistant but not included in the template so far. From this list the instructor can select those building blocks he wants to include in his template.

Figure 1: Editor for adapting course templates

Runtime support. The templates describe possible ways of performing courses online while their building blocks provide appropriate system functionality. This runtime system, i.e. the adaptable course assistant, provides access to the web technology as implemented by the building blocks of a template, and functions for managing the course (in some aspects similar to a workflow management system). This is implemented by generating, based on the template description, the runtime component and its user interface. Hence, for each building block the assistant provides access to the respective functionality. For example, according to the template depicted in Figure 2 (a) the assistant enables to invoke those functionalities implemented by the building blocks of the basic template Figure 2 (b) depicts parts of the generated user interface, within which the instructor gets access to the functionality, for example, of the building block "VU Sperre".

(a) modified basic template

(b) user interface of the runtime system

Figure 2: Dependency between template description and runtime support

Discussion

Starting with the development of the first prototype of the Virtual University (Buhrmann et al. 1997) the usergroup of the instructors was analyzed. As a result an increasing demand for tools supporting the tasks of the roles course designer and course administrator was identified (see also Biedebach et al. 2002, Feldmann & Schlageter 2001). In the following special components allowing dedicated support like the Seminar Assistant (Biedebach et al. 2001) and the WebAssign (Brunsmann et al. 1999) were developed. The Seminar Assistant aids instructors in conducting virtual seminars and allows easy utilization of the required internet services. Its implementation, however, is based on a very specific type of course, preventing its adaptation to other kinds of virtual seminars. The system WebAssign allows to perform online exercises and can be used within different types of courses. It represents a special "building block" and was developed separately, such that direct integration into the whole platform is not possible easily.

The approach of adaptable course templates proposed in this paper allows adaptation of planned course types to individual requirements. The system helps in selecting and utilizing Internet and web technology, respectively, to enhance distance education. For that purpose it provides different templates showing how a course of a special type, e.g. a content teaching course or a virtual seminar, may be executed. Each template can be altered to meet the special needs of a course and the individual ideas of its instructor. At runtime it provides access to the web technology as implemented by the building blocks constituting the template. Furthermore, functions are available for managing the course (like a small workflow management system).

BEST COPY AVAILABLE

A similar approach is provided by TeleTOP (de Boer & Collis 1999), within which web-based course-support environments are generated. Similar to our assistant all courses have a common interface design, but differ in their chosen functionalities. In contrast to TeleTOP our assistant provides not only pure building blocks but also diverse templates depicting established ways of running different kinds of web-based courses.

Workflow management system technology is also investigated in other approaches aiming at tool support for instructors. There it is employed to coordinate e-learning activities within a single course, in particular in conjunction with groupware tools to manage collaborative learning (e.g. Medélez et al. 1999). However, in these environments the underlying model is fixed and thus not adaptable to different course structures and types.

The described software assistant will be a part of the platform of our university, thus integrating this approach into a general environment which also supports organizational aspects (business processes). Our current work is aiming at the implementation of an assistant supporting students of the university. Its runtime system will also be based on the course templates specified by the instructors.

Virtual University of Applied Sciences – German Flagship Project in the Field of E-Learning in Higher Education

Rolf Granow , Michael Bischoff; University of Applied Sciences, Luebeck

1 Introduction

In 1997, the German Federal Ministry of Education and Research started an initiative to promote e-learning in Germany by installing an extensive research program. Actually, more than 100 projects have been funded by the German Federal Ministry of Education and Research in the field of e-learning in higher education. Three of them are so-called Flagship Projects, of which the Virtual University of Applied Sciences in Engineering, Computer Science and Economic Engineering is the most prominent, and with DM 42 million the best funded.

Officially begun in 1999, its origins go back to 1997 when the faculties at Luebeck University of Applied Sciences set up a working group on online education. In October 2001, the study program of Computer Sciences started in seven joint universities of applied sciences with six courses. In the meantime, first results are available. The second study program, Economic Engineering, will start in winter semester, 2002.

2 Presentation of the Project

Twelve universities of applied sciences, two universities, federal employees' association, unions, and businesses of seven federal states are involved in the development of the two complex online study courses Computer Sciences and Economic Engineering.

2.1 Objectives and Project Tasks

The ambitious goal of the project is to form a virtual organization of ten existing campus-universities of applied sciences from six German federal states[1]; in essence, this means a decentralized and distributed management.

The responsibilities of each of the involved universities are precisely defined, i.e. for administrative services, technological support, deployment of the common curricula of the study programs, development of courses and learning objects, instruction and tutorial support etc. The design of each of the courses is always incumbent on only one chosen member of one of the involved universities. Later on, the complete course will be adopted by all participating universities. All courses are being approved jointly. Suitable modules from commercial vendors may also be employed, provided they meet the required quality standards. The traditional unity of course design and teaching is thus partly abrogated.

The conception of the Virtual University of Applied Sciences is based on the combination of multimedia course materials, a professional online tutoring including students' coaching and group working and a sophisticated administration of the whole study program.

The last-mentioned topic required the choice of a suitable learning and administration management system which would be able to combine the individual demands of the universities due to their inscription and student management modalities as well as a flexible tutoring of the students by their professors and tutors, and to offer sufficient communication tools for the social and course specific exchanges between the students.

---

[1] For a list of participating universities see www.oncampus.de

The large amount of about 60 subjects to fill the curricula of the two study courses made intensive research efforts necessary in order to deliver the technical, ergonomic and didactic fundamentals for a common and high standard of the course material and concepts. The common conceptual guidelines for the subjects should furthermore take care of the individual didactic belongings of course subject and the responsible experts.

For the implementation of the study courses in the participating universities, the instruction of the teaching and tutoring personnel as well as the foundation of common working groups and specialist peer groups had to be taken into account . First experiences which delivered the knowledge for this part of the project had been collected during the pilot phases of the first developed courses.
In the meantime, nearly 35 percent of the courses have been finished. Most of them were tested in pilot trials with distributed students. With the results of these tests, quality criteria and procedures for the courses at the Virtual University of Applied Sciences could be determined. On the basis of these experiences, all students and tutors involved are integrated in a well developed evaluation system which enables the continuous optimisation of course production and course maintenance.

2.2 The Virtual Campus Association of Universities of Applied Sciences

The Flagship Project will provide the courses for the common study programs up to the end of 2003. To run these study programs is task of the involved universities. To achieve this, in April 2001 7 of the universities founded a consortium, the so called "Virtuelle Fachhochschule", which has been offering the study programs to online students first beginning in October 2001.

Forming this virtual organisation, the universities defined and agreed on the rules of cooperation, of handling the intellectual property rights of the learning objects, of responsibility for quality of learning objects and tutoring, and of financing the future activities.

The responsibilities of the universities in detail affect for example the sustainability of the course range, the rights on the course materials, the use of the learning management system, the commitment to the maintenance of courses, and the organisation of students' inscription.

The universities of the consortium signed a contract on these topics to be able to run and sustain the study programs in the long term. Partners of this consortium are those universities within the project that have started or soon will start with at least one of the common developed study programs. The conditions of the study programs are equivalent within the whole consortium. So students normally apply to the university where they want to have their residential periods.

The common organisation is gradually being reduced to an optimum, a process being ruled by the federal legislation, the individual needs for autonomy of the joint universities, and by economic criteria. So after the end of the project, there will only remain a small common bureau for the joint universities which will be responsible for the technical support, marketing and data management.

The administration of students, tutors and professors as well as the running of the courses and the maintenance of course materials will be the responsibility of the single universities.

3 Conceptions of Learning and Teaching

3.1 Course Materials and Course Tutoring

The online study programs of the Virtual University of Applied Sciences are especially directed to students who have an essential need for flexibility regarding time and space as a prerequisite in taking up a university course.

The curricula of the programs are strictly modular and based on the European Credit Transfer System.[2] A modular study program at the Virtual University of Applied Sciences, e.g. Economic Engineering, consists of several courses, for instance marketing, accounting, logistics etc. It is being stressed that the approach favours student-centered learning. Final examinations (in the end of each course) are identical at each of the universities.

A typical course consists of 80 percent e-learning components and 20 percent face-to-face encounters. Students are not isolated while doing an online course and using interactive course materials. Professors and tutors, especially trained for the demands and needs of online students, guarantee regular contact and qualified advice. Communication with fellow students in the virtual learning room enhances the learning process.

The training of the tutors and online professors aims at teaching the different special skills necessary to carry out online courses instead of face-to-face lectures. Partly, these are technical and organisational abilities, as for example the handling of hard- and software, communication and information tools of the Learning Management System (LMS), the organisation of course materials and the administration of student groups. Concerning technical questions, the tutors should be able to offer a first level support in order to support students during their working processes.

Furthermore, tutors and teachers have to learn how to compensate the restrictions of web based learning. These can be missing awareness and missing social contacts with other students, missing direct reactions to open questions and misunderstandings. These shortages are disadvantages of the online teaching and learning and can lead to demotivation. To compensate these disadvantages teachers have to learn to apply very consciously and carefully specific social and pedagogical measures. Students have to be motivated for and integrated into the learning processes. They must learn to use the flexibility of web based training but also to accept the specific requests of the medium. That is what the teachers have to do. A special ability to learn is the initiation and moderation of virtual group works via the internet and LMS.

Virtual group work is an integral part of the didactic concept of the Virtual University and integrated in several study courses. Students are building a network of specialists whose communication and competence extends beyond the demands of the study program.

The online study is complemented by various residential periods that also strengthen the social components. Residential periods are organised by the respective university and - as a rule - take place as compact seminars in the weekend. Within the consortium, practical training, lab work, tests and/or final exams take place during residential periods.

Each course contains a large amount of multimedia course materials. Typical elements are html pages, flash animations, graphics, sounds and video. These elements are completed by scripts, links, online books or databases.

The content of the course material is selected by one responsible expert, normally a professor and member of one of the joint universities. The content and the design of the course is fixed in agreement with a peer group of colleagues from partner universities. At least one member of the peer group is experienced in the design of e-learning courses.

---

[2] For further and detailed information on the study-programs and their courses see www.oncampus.de

The production process was developed over the first two years of the project, heading for a constant and continuous quality. It includes the design of a prototype of the course on the basis of a common and quite complex styleguide and a multimedia catalogue. The prototype is evaluated by expert groups concerning didactic, technical and ergonomic aspects.

After a common review and discussion of correction measures, a team of multimedia producers writes the story board and subsequently produces the whole course. The last step is the testing of the course material in a pilot phase.

During the term, these especially developed course materials are supplemented by additional assignments and partially by group works and case studies.

Pursuant to the European Credit Transfer System each course (5 credit points) is designed for a working load of 150 h.

3.2 The Learning Management System

The delivery of the course contents is decentralised and spread to different universities. Each university that matriculates students to the common programs must have access to the whole course program. To get a high availability of all the courses and a cost-efficient system design, the operative systems work on a common server architecture with a common learning-management-system. The servers are designed with back-up systems on different locations, using existing net resources with high-speed access.

As a common learning-management-system, a standard application was achieved. After an evaluation of different systems, the Blackboard V level III-software was installed for the needs of the whole consortium. The performance and scalability of the system was tested in pilot applications for 3 semesters.

The production of course materials for self-organised learning is independent from this platform, so that the learning objects can also be used in other environments without redesign. To improve the course production some specific tools had been provided, especially for navigating the learning objects, including glossary and annotation functions.

During the evaluation, 15 platforms for the learning management system were analysed. 8 of them were installed and tested in the project. These were the products: Lotus Learningspace (IBM), CourseInfo (Blackboard), WebCT, Pathware (Macromedia), LUVIT, TopClass, Gentle (Hyperwave), DLS (ETS-Online).

The selection of the LMS was done on the basis of common criteria such as[3] Web Browsing, Asynchronous and Synchronous Sharing, Student Tools, Support Tools (Course, Lesson, Data, Resource, Administration, Help Desk) and Technical Administration (Server Platform, Client Platform, Limitations). The criteria were weightened with highest values for the communication tools and administration facilities. These facilities are of high priority for the cooperation and common course running of the joint universities. Three products were proven in pilot tests: Lotus Learningspace, Gentle, and Blackboard. As a result of the evaluation in 1999, the Blackboard System was chosen as platform for the project because it achieved the highest total evaluation score. In the detailed analysis it fitted best according to the demands of students' administration.

---

3.3 Computer Supported Collaborative Learning

One of the project's working groups is involved in the development and testing of Computer Supported Collaborative Learning, especially supported group learning. In this context, an interesting new form of online collaboration, called the jigsaw method, was carried out.Group techniques and methods show great promise in the learning effects, also in Computer Supported Collaborative Learning (CSCL). These should result from the perspective of cognitive elaboration, the construction of shared knowledge and the possibility of multiple perspectives. However, previous results in this field of research were not very extensive. Therefore a jigsaw was started in CSCL.

The jigsaw method is a group work teaching process which is well known in traditional classroom learning but new in online teaching. The method bases on the working on a topic under different perspectives and with different intentions. One instrument to reach an intense preoccupation with the topic is to mix the groups at least one time and to force the members of the new groups to represent and defend the results of their former groups in order to find to a new synthesis. The jigsaw method is carried out in several phases, with each of them resulting in a concluding report or a group statement.

During the course of 'Environment-oriented Management" (EoM) (subject in the study course Economic Engineering), the different assumptions and suppositions of the effect of the jigsaw method were tested. The case study focused on the evaluation of the degree of collaboration and the influence of the group method. The result was that jigsaw proved to be an efficient method of intensifying collaboration in CSCL. However, there are certain conditions to be considered. Facets like group cohesion, individual competence, and awareness have a significant influence on the result of the jigsaw.

3.4 Cooperative Teaching

Teaching at the Virtual University of Applied Sciences is a cooperative process. It starts with the foundation of one expert group for each subject. This group comprises one responsible expert of each university which offers this subject. Normally, these expert groups meet for special training programs in online tutoring, designed for the members of the joint universities. The expert groups discuss and balance the details of the course tutoring, the residential periods and the final assignments. These steps need a very intense process of discussion.

Despite several differences in the expert groups concerning the subject details, by now it has been possible to reach a cooperative teaching for each of the offered subjects. . This can be regarded as a real success of the project. The chosen model for the course tutoring which was installed seems to allow a rather satisfying degree of individuality for the participating experts on the basis of the common course materials.

4 Running of the Study Course Computer Sciences

4.1 Organisation

The Bachelor study program in Computer Sciences started in winter 2001 with about 200 students at 6 universities. Participants in the tuition fee-free Bachelor degree program will graduate after six semesters, a Master's candidate after additional four semesters. These study programs are part of the regular studies of the universities.

A concept was generated for sustainable financing of these study programs regarding the costs for

- permanent updating of the courses

- online-tutoring
- residential phases and
- organisation of the consortium and common services.

The virtual organisation is dedicated to the purpose of developing and offering common online study programs and of optimising the use of the courses for study as well as for further education. For using synergies, this virtual organisation is related to the existing academic organisation of the member universities. The online programs are implemented in the existing departments and professors of these departments are responsible for the residential periods and the quality of the tutoring.

The virtual organisation is defined on three levels:

- on the management level, the heads of the universities form a common board for all fundamental decisions
- on the department level, the heads of departments form a common committee for each field of study program: one for Computer Sciences and one for Economic Engineering.
- on the course level, professors from each department who are engaged in the same field form a common committee in which one is responsible for the availability of the modules for the whole consortium. The other members bear the local responsibility in their courses for their students concerning online as well as face-to-face tutoring.

4.2 Experiences

As one of the first results from the pilot phases in different courses and from the profiles of the online students enrolling for winter term 2001, it can be stated that these new kinds of study programs are accepted mostly by people who want to do their studies and jobs in parallel.

The online students at the University of Applied Sciences differ significantly from on-campus students: they are older, they have got jobs, and above all, they appreciate the flexibility that e-learning provides. This is not the case with many on-campus students who, as several tests showed, did not take advantage of the flexibility and instead accessed the online modules from the schools' computer labs during regular office hours. This might, in part, be explained by the still high costs for Internet access at home. Most of the on-campus students preferred the traditional face-to-face teaching.

Thus, the study program of the Virtual University of Applied Sciences does not compete with existing higher education, but rather supplements the range of teaching methods and courses available.

One positive aspect of the network for the universities is that not every institution has to fund and develop costly web-based study courses on its own. Consequently, even the medium-sized and small universities of the network will now be able to offer attractive online study courses.

5 Conclusion

The project Virtual University of Applied Sciences shows new ways of qualification models in higher education. It enables universities to reach new customer groups. The traditional universities will be able – following the model of the joint universities in the project – to step into this market using the economic advantages of cooperative teaching and course administration.

One of the main advantages of this project in comparison to others is the extensive course material which is produced during the runtime. This material enables the joint universities to create several new study programs using parts of the existing material combining it with new course contents. So the project will be the nucleus for universities reacting very flexible to demands of the labour market.
Future aspects of this project will be the internationalisation and the expansion into new study courses.

raj.boora@ualberta.ca

Abstract: To travel is one of the greatest ways to learn about the world. It is the "getting there" that provides the learning experience, not so much as the destination itself. Education is also a journey, one that should last a lifetime. But for many students today it is one that lasts only for as long as they are in the classroom. In such short trips, many students do not see themselves going anywhere. The new paideia offers a means to allow students to once again find their way.

Ideas From History

A seasoned traveler will often understand where the road is leading judging by where the road has been. Looking back down the road of education, the road may have begun in Ancient Greece, with Aristotle.

Aristotle felt that an important key to education was communication, and the ability to move the hearts and minds of those who were being spoken to (Neal, 2001). Giving students relevant instruction was both vitally important and successful for Aristotle. One of Aristotle's greatest students, Alexander (the Great) learned these lessons well (Popovic, 2001). Alexander brought forth the Hellenistic age, and with it paideia: the idea of lifelong learning. Paideia, was a journey of discovery throughout an individual's life. It created the world as a classroom and every day as an important and relevant lesson to be learned. Within paideia, learning was a lifestyle.

Looking up the road from Aristotle, we find Dewey. His ideas regarding educational reform are still influencing us today. Dewey believed, in a Hellenistic manner, that school should be a life long process, an extension of society within the classroom (Field, 2001). Dewey also acknowledged that progress was vital. Keppel (1990) noted, "[Dewey] taught us that the only danger confronting us is being closed to the emergent, the new, the manifestation of progress." If Dewey was correct, then classrooms in general, both online and offline have committed a folly in not changing significantly over the course of the last few decades. Classrooms are seemingly stuck in time without computer-mediated communications and in a world that does not value leisure.

The Destination

A positive attitude is important for success in any endeavor. If education is to create successful students in today's world, then a positive attitude must be created in these students. Creating this positive attitude will require teaching classes in a manner that is relevant to today's students. Connecting the classroom with the outside world will create a journey that does not start and stop in the classroom, but continues throughout life in the tradition of paideia. Here learning is a process, a journey that one takes, not a trip that one is taken on (Volman & van Eck 1995; Basile & D'Aquila, 2002; Hatcher & Hinton, 1996; Connolly, McMaster & Hatchette, 1999).

A Start Down the Path

Some elements of the paideia paradigm are already in use in many classrooms. Active learning and constructivist learning models are used to help make the classroom an extension of societal elements. Generally the use of these methods is limited due to resources, but it is successful in presenting the material being taught to students in a largely holistic fashion (Lunenberg, 1998; Roberts, 1998). These instructional paradigms can peak the interest of students and encourage them to follow a potentially life long journey of exploration. Students starting on this path might likely find the journey it's own reward.

The dominant mode of instruction is still, however, an instructor centered model; one where information is broken into pieces that are easy to present and easy to assess. It is a cold and efficient process to deliver information to a large audience. The onus is on the student then to reconstruct the whole from the parts that are presented. Often students never succeed in this task and become uninterested in what is being presented (Lunenberg, 1998). Within this mode, the student is merely being taken to the destination, experiencing a cold and impersonal journey with the destination as the only goal.

Elements of the New Paideia

Blending the successful elements of active learning and constructivism, the new paideia uses communication, empathy and community to overcome the issues that currently plague the educational system. If used appropriately, more students may be encouraged to explore and enjoy their own personal life long journeys of learning.

Communication

Within the new paideia, communication is an omni-directional exercise. Everyone involved with the class has an equal voice (Roberts, 1998) that can be expressed freely inside and outside the classroom. Regardless of age, students frequently engage in social conversation. By the time a student is in post secondary education, they often spend an equal amount of time in social conversation as they do in the classroom (Neal, 2001). Instead of trying to control this communication, instructors should seek to use it to their advantage, seamlessly combining the discussion of social topics with classroom material at all times.

Empathy

Empathy is an important social skill, encouraging individuals to be responsible to themselves and to their community (Roberts, 1998). This is a skill that is encouraged in early childhood education and later in professional school. But between these two extremes, there is little use of empathy in the classroom.

Empathy seems to be an innate human ability so it is odd not to include it throughout the educational process. From birth, young children are seemingly able to have a "feel" for the experiences of others. Empathy in a classroom is vital because it allows individuals to gain an understanding regarding their own thoughts and ideas by experiencing the opinions of others. To gain the appreciation of other individuals in the class, students must first be encouraged to deconstruct their own ideas. The class then shares these ideas to arrive at a communal understanding of various topics and opinions (Burns, 2001).

Community

By sharing ideas, a community emerges. Communities are powerful tools that benefit individuals by providing a place of safety and belonging. Within the new paideia, this is a community of learners. Belonging to these communities requires only the open exchange of ideas and through these communities society becomes part of the classroom.

Once internalized, students as learners become self-directed to seek new ideas to add to the community and are rewarded intrinsically through these contributions (Hatcher & Hinton, 1996; Howard, et. al., 2000). Hobbyist and researcher communities are prime examples that these communities exist and work.

Fusion: Technology and Paideia

An effective way to look at various technologies, including computers, is to see them as extenders of human ability (Kritikou, 2000). The most important ability that computers can be used to extend in terms of the new paideia is an individuals' ability to communicate. In extending this ability to communicate, all elements associated with communication are also extended, allowing for the classroom to exist at all times and the life long journey of learning to continue non-stop.

Often computing technology is merely an add-on to the classroom and in this manner it is very ineffective (Strommen & Lincoln, 1992). The key to using computers effectively in the classroom in terms of the new paideia is to integrate them into the way students and instructors communicate within the class. From this point, all other ways and means of integrating computers into the classroom will emerge.

The popularity of email and instant messaging provide good examples of how technology can be integrated into the classroom. Students and instructors become available to each other at all times thus allowing for the seamless interfacing of the classroom and the outside world that was mentioned before. It is likely that with a bit of encouragement, students and instructors would find ways to include multimedia elements in their communication and before long, computing will become ubiquitous inside the classroom as it is outside the classroom (Burns, 2001; Rice & Wilson, 1999; Varvel, 2001).

Leisure – The Modern Paideia?

Judging by the amount of money that is spent worldwide on the pursuit of leisure, one would think that its influence would be far reaching. However, it seems that the reach of this human desire to play stops at the classroom door. Play is seen to be disorganized and primitive, not suited for the classroom that aims to teach the virtues of civil and ordered society.

When individuals play, alone or in groups, they learn. They become self- motivated and self-structured, able to take what they learned in the past and apply it to novel situations (Bower, 2000; Strommen & Lincoln, 1992). Today many of the toys that are being played with are technological. So again, not fearing progress, it would be wise then to bring this technology into the classroom and use it to teach students (Soloway, 1991). Using communication technology, students can "play" with ideas; creating interest where there was once none.

To affirm that these ideas for the road ahead are sound, we can look back at the work of Aristotle where leisure is identified as one of three forms of paideia (Kritikou, 2000). In play students can create their own knowledge as they interact with their peers, instructors and educational materials to arrive at ideas that they can offer to their classroom community (Roberts, 1998; Rice & Wilson, 1999; Seeler, Turnwald & Bull, 1994). At the same time as they play, students chart a personal journey exploring the materials presented to them.

Application to Online Classes

The challenge is to apply a way of life to a single course, a point in one's life. To accomplish this task, one can approach the delivery of the course as an attempt to create a habit. Starting from the first class, showing students how communication permits empathy, which creates community, is important. The goal of the instructor is not to make the course compete with other elements in the life of the student, but rather to integrate into them in an active fashion. Thus they encourage students to view the course as a place to make a number of new friends that are sharing the same experience for a time. Completing the course becomes a matter of working with these new friends to complete a task that requires the unique talents and ideas of every student in the class.

Application of the new paideia to courses that are offered online begins with communication of ideas among the members in the class in a free, open and supporting manner. Students and instructors alike share ideas and concerns, creating empathetic relationships between individuals. These relationships blossom into the establishment of the learner community that extends beyond the course.

Some number of social or leisure-like elements must be integrated into the course. In this formalized "play" students are allowed to explore the material as a group, gaining the advantages of motivation and self-direction that are gained by group participation. As students begin to play with material that is increasingly relevant to their own lives, their abilities grow and they become ready to engage new educational challenges. Without a social element being included in a meaningful manner to the course, the advantages of the new paideia such as self directed exploration from within learner communities will never emerge. A suggestion for this is to use email lists rather than requiring students post a message to a Web board or similar system in their first week. In this way the communication comes to the student in a manner that is more personal and akin to conversation. Rather than forcing students to go out to a specific "place" to meet and greet, every individual in the class will be able to communicate from where ever they are. Often for those who are online, this location will be from their email inbox.

Limitations

Online courses must however be wary of the issues involved with class size. It may seem to some that the upper limit to the number of students who can enroll in an online course is limited only by the capacity of the servers to distribute the material and the markers to mark the material. But in light of the new paideia, this is an oversight. The maximum number of students is equal to the maximum number of individuals who can be meaningfully incorporated into the learner community. Personal communication must be present between all members of the class and all ideas and feelings must be appreciated and used within the knowledge base of the learner community.

The other issue that should be addressed is that of the staff's workload. In an online class the only way that an instructor can know that too much work has been assigned is if the students complain; however, students are often too burdened by their workload to protest. Paying attention to the social activities and communicating personally with students should help address this concern.

Conclusion

Like the traveler at the end of the journey, the destination is often a chance to look back on the road that has been traveled. Education in general is facing a major dilemma as students are becoming less interested in what goes on in the classroom. Often citing that the material covered in the classroom does not pertain to them or is not enjoyable. They find themselves in classrooms that have not changed significantly from the time of their parents and all the while, society outside the classroom is evolving faster each day.

The solution for education is to follow society's lead. The new paideia offers a means of achieving this by using communication to create a community that goes beyond the classroom or the monitor. Students feel like they belong in a community where the material that they are learning is relevant and where they stand as individuals are important. Appreciating that learning is a process or a journey where the path taken to the destination is at least as important as the destination itself.

Online and offline, the new paideia may be the solution to the problem of what is missing in education today. The new paideia brings to the classroom a learner community that uses leisure and technology to integrate course material into the lives of students.

Abstract: The shift to new paradigms in education pushed by new media has initiated a critical re-thinking of the way we talk of and practice teaching and learning which is still open. Some concepts of the Western educational tradition can be helpful in finding a new way of integrating IT in learning. This paper propose to consider knowledge as a relationship and shows how this provides helpful insights in instructional design and in the exploitation of new media in education.

Introduction

During the last decade the communities of educators and instructional designers have experimented the impact of IT in their professional activity with an impressing rush. The shift to new paradigms of education has been accompanied by great hope and many hypes. Mixed to real opportunities and to a sometimes ideological debate, something has actually happened: maybe not in the way we teach and learn, but in the way we consider and understand education. New technologies have acted as a catalyst on the way we think about learning and teaching, on the categories we use for designing and talking about education. New media have been the impact wave that rumbled the system and brought to a conceptual paradigm shift in Western education, concentrating and empowering the forces that were already latently in motion. Nevertheless, while the aggressive speed of technology gave a first impulse to the shift, it left little energy for a thorough rethinking of education. Issues brought from the Psychology and Education communities are the topics for a discussion which is still open and lively.

This paper proposes a first description of a new approach to curriculum design based on a traditional conceptual framework. Goal of this paper is to bring a theoretical contribution for interpreting the development of educational technologies and integrate them into the Western teaching and learning practice. The basic understanding of learning and of knowledge is in fact the soil in which the plant of a well-shaped education system can grow, thus we propose to consider some of the issues raised by e-learning going back to the roots of traditional Western educational theories. Maybe surprisingly, this approach does not end up in a conflict, but offers a fruitful mindset and several high-level design principles for new learning environments.

Knowledge as a Relationship

Knowledge is one of those words that anybody understand effortlessly until required to provide a definition, just like *conscience*, *I*, or *time*.

In the last decades, Information Systems and - more recently - Knowledge Management literature proposed a vision in which knowledge is produced, stored and retrieved. Managing knowledge with IT systems is indeed a process which much resembles a production chain, and modeling such situations actually requires a precise definition of knowledge. A certain overstatement and unclear understanding of these disciplines have brought to the spread of such metaphors outside their application domain to that of curriculum design and education, specially in the field of new media in education. This conception of knowledge, though effective in many contexts, does not fit completely and hides ambiguous implications for an educational system.

Outside conferences in fact we talk of knowledge in quite another way. We mainly use a verb, more than a noun, the latter being the abstract word we use when we need to substantiate the action. "Of course I *know* him, I met him last month in Wandsworth" "Wandsworth? Oh, yeah, I *know* where it is. It's near Clapham, isn't it?" In common language, *to know* is the action involving knowledge: a subject and an object of knowledge are put in relationship by this verb.

BEST COPY AVAILABLE

Classic philosophy and medieval scholastic considered knowledge as a relationship between a *subject* person and (a part of) reality, an object, a place, an invisible essence or another person, that we call a *knowledge object*. Learning was conceived as a dynamic through which this relationship was put into place. Taking that perspective, on the track of authors who reproposed it more recently such as (Lonergan 1957) and (Lonergan 1990), we claim that knowledge has the status of *relationship*, which is an activity of a person's and can not be stored, codified in bits and measured - at least directly. What can be measured, stored, retrieved and transmitted, are data and information, which are the basic part of a more complex phenomenon called knowledge.

This approach to learning and knowledge is insightful as it concerns the exploitation of new technologies in education and provides powerful concepts for tackling many design issues.

Cognition as Establishing a Relationship

Cognition is therefore a process aimed at establishing effective knowledge relationships between the subject and the world. Learning can be modeled as a dynamic occurring on three levels: experience, understanding and judgment.

At first, learning could be described as a process with three main steps, each of them defined by the specific questions concerning the main knowledge object (Lonergan 1990)

- *Experience* is the level in which the subject perceives the object. Perception is to be understood as a partially unconscious but active process, such as in the research track initiated by the New Look (Bruner & Goodman 1947) (Bruner & Goodman 1949). This is the level mainly addressed by Dewey's work in the first part of '900 (Dewey 1900) (Dewey 1938), who considered schools as the place where an intensive experience of the world could be made.
- *Understanding* is the level in which the subject asks "what is it?" or "how does it work?" and develops an enquiry until he/she "gets it", i.e. reconstruct a mental model for the specific knowledge object she is considering, eventually afterwards reworking it as a concept through generalization and abstraction. This is the level mainly concerned by the current work of Constructivism in education.
- *Judgment* is a further level, often unconsidered but essential, in which the subject turns to the acquired understanding or concept and asks "is it true?" or "is it adequate to my experience?". This step requires the gathering of evidence (as recognition of fact, or as activation of previous knowledge) in order to accept the model constructed by the learner: thought is transformed in knowledge.

But learning is of course not only a process, but a dynamic (as represented in Figure 1) in which each level is influenced and influences its neighbors. Concepts and understanding e.g. influence our perception in a "top-down" manner, exactly as previous knowledge on the level of judgment influences concepts and understanding

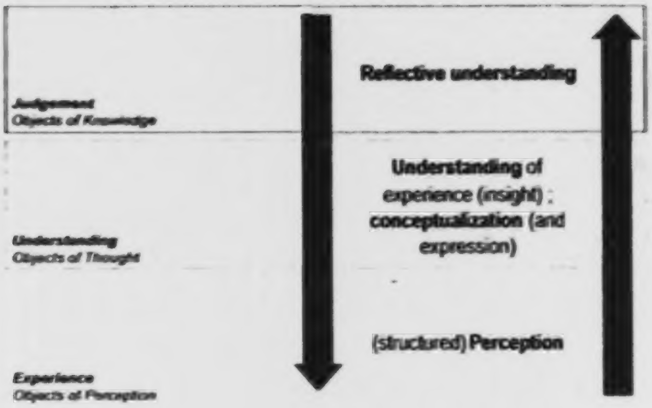

Figure 1 - the learning dynamic

A more detailed of this model, here just sketched, can be found in (Lonergan 1993). Considering learning with an interdisciplinary approach, it is interesting to see how this traditional insight matches and merges with more recent studies and with current information and communication theories, e.g. memory studies - remarkably (Glenberg, A.M. 1997) - or cognitive science, like in (Brennan 2002), (Staudinger & Joos 2000) or (Carassa & Tirassa 1995).

It is clear, and it is one of the greatest gains in the current educational discussion, that this process is undergone *in primis* by the learner. IT can not guarantee learning, but may help establishing or renewing knowledge relationships by managing adequately data and information, providing support for conceptualization and creating a favorable social environment.

Properties of knowledge

Considered this way, knowledge presents four basic properties:

- Knowledge is *synthetic*: real knowledge, as real relationships, is somehow "natural", and in act is not reflexive. We really know something when this shapes our action: knowledge, as any kind of relationship, is actually owned inasmuch it becomes a habit [1]. A knowledge relationship is an operative synthesis of experience, understanding and concepts.
- Knowledge is *inter-connected*: each bit of knowledge is not independent in one's mind: in non-pathological situations, all of them should be harmonized, put together in order to form a consistent whole, one unitary vision of the world. This process was described e.g. by the piagetian concepts of ***acquisition*** and ***accomodation***.
- Knowledge is *extra-connected*: human understanding and knowledge operate on the dimension of totality. Any experience – which is the only source of knowledge – is positive if it opens, requires, and introduces to other new experience (Dewey 1938): one bit requires, like magnetic attraction, to be completed with other knowledge. The extra-connectedness of knowledge is therefore a reflection of the innate human curiosity and attitude toward learning, and on the other side, of the (perceived) connectedness of reality itself.
- Knowledge is *current*: as relationship, knowledge develops and has effect in the *hic et nunc* of an action. Once acquired and established, knowledge can become somehow latent, like a relationship with a friend we seldom meet: the relationship still exists but is like asleep. In the same way, we know objects we do not handle any more, e.g. because we have changed our job place. Knowledge

is still there and still interacts with other knowledge bits as part of the whole interconnected system, and still suggests new experiences to be acquired as part of the extra-connected system.

We will show in the following paragraphs that this perspective allows powerful insights in learning and in designing and managing learning with new technologies. IT are in fact tools that can play a role in learning.

New Media in Education: Tools for a Relationship

In the proposed perspective, learning is the *activity* of establishing a knowledge relationship, and as such requires a subject actor, some one who holds the ends of the process and execute it. In order to be a real and complete activity, the whole subject should be involved, i.e. his/her reason, will and affection [2].

Consequently, none can learn for someone else: like eating or breathing, none can do that for us. Put it the other way round, none can grant that someone else will learn, as personal freedom is required. As a good teacher is not a warranty for his pupils to get a graduation, educational designers should keep in mind that no structured learning environment or skilled tutoring system can grant success. Even more, no technology allows let us to take knowledge acquisition or creation for sure. Everything can help us, support us, let us learn more easily and quickly – nothing can take our place.

In this view, new media represent powerful tools. The simple fact of providing a more structured and rich environments can in fact be a help for learning. On the other hand, several studies from cognitive science (Light & Light 1999) and web usability (Stover, Coyne & Nielsen 2000) have proved that learning to use a technological apparatus is a job in itself - both for teachers and learners. This is one reason why with IT good students perform even better, while the other still lag behind. In any case, we have to discard many of the e-learning hypes stating "learn faster, learn better" or "increase your knowledge". Moreover, IT have higher *affordance* as media (Clark & Brennan 1991), and so are more likely to be actually used by learners only when really necessary for more effective learning.

How can this issues be addressed from the point of view of curriculum design? In this paper, three general topics will be discussed: the definition of a role for new media in a real educational environment; user-centered design and adaptive systems; teaching roles in educational environments.

Defining the Role

New media, as tools that may be exploited in teaching and learning, should be carefully controlled and managed. The complexity and power of technology has revealed the necessity for a more structured process of instructional design, and requires the interaction of different professional profiles for an effective implementation and management (Harasim et Al. 1985). All this effort is rewarding only if these tools are properly introduced for supporting educational activities.

A structured model of the learning process as the one proposed above can be used as a sort of map for planning such introduction. At any moment in the learning dynamic, tools can be used for supporting the current status, e.g. conceptualization, reflective understanding, etc. This allows to define exactly what is expected from a technological system, and - most of all - what cannot rely on the system.

For the course *The Institutional and the Society*, given for 180 freshmen at the Università della Svizzera italiana, the Istituto Comunicazione e Formazione developed a set of 22 online multimedia case studies offering texts, video and audio materials taken from newspaper, radio and TV programs, describing the nature, goals and activities of different institutions (e.g. UNO, Amnesty International, etc...). Goal of the digital media support was to provide "live" portraits of the institutions, to be matched with the theoretical approach offered during lectures. Their use was planned at two levels, according to our model:

Objective 1	Providing an overview of real and active institutions: on the level of *experience*, the digital materials were used to let students make acquaintance with the object of their study;
Objective 2	Offering real case-studies: on the level of *judgment*, the external description of institutions could be used for verifying the matching of theory and practice.

---

[2] This is true also from a juridic point of view: any suspect will not be condamned if he was not able to understand what he did, or if he had done it not freely, e.g. under direct menace.

During Summer Semester 2002, while such materials were in use, the teaching staff encountered some mismatch between their expectation and the actual results being performed by the students [3]. While students got perfectly the importance of the digital materials for more concrete and practical perspective of the course (objective 1), they had difficulties in analyzing with some degree of detail the case studies (objective 2). The structured requirement analysis briefly reported above was then the possibility for tracking the causes of the problem, and the model of learning was a way for interpreting them and figuring out a viable solution.

The missing step for objective 2 was a lack of understanding of two elements:

1. The case studies in relation with the concepts proposed in the course: students did not have the time to grasp the concepts in the course *before* working on the case studies, so that concepts where no help in getting an insight of the particular institution being analyzed.
2. On the other hand, the great complexity and variety of institutional communication made it difficult to define concepts inductively, starting from the case study itself in order to re-construct the concepts.

This analysis allowed to define specifications for a redesign of the digital materials and of their introduction in the course (they are currently under revision and will be implemented in Winter Semester 2002/2003). Each case study will present a sort of "introductory path" leading the students through the main digital materials and providing one working hypothesis for a more structured analysis and understanding of the single institution. Moreover, one lecture will be devoted to work with groups of students on one case study, so to show how the connection theory-practice can be achieved.

User-Centered Design and Adaptive Systems

User-centered design is a concept, taken from engineering and interface design, which is being successfully applied to education. Curriculum designers should be concerned with making learning more effective and attractive, and this can not be done without considering the peculiarities of each learner. We have to consider that in a lifetime, a person will pass through a number of knowledge re-structuring steps, when new knowledge relationships are integrated with previous knowledge, forming one whole dynamic and interconnected system (see above). Any single act of learning belongs to a history and concerns all previous knowledge. Moreover, each of us has a personal way of learning and a different mix of learning styles (Kolb 1999). Each learner is unique, in him -/herself and for his/her personal history and knowledge relationships.

Yet it should not be forgotten that knowledge relationships have two poles: the learner on one side *and* the object on the other. In a real situations, this means a discipline, learning materials, and a teacher. User-centered design means a stress on the learner, which nevertheless should not forget the other pole. Even more, it should focus on both of them as a system.

In designing an education system, the learners' previous history and learning style should be taken into account. Adaptive hypermedia systems (De Bra & Calvi 1998) (De Bra, Houben & Wu 1999) and student modeling research (Kay 2001) consider these issues, which on the other hand can be included also in less sophisticated educational environments design. Tutoring and mentoring describe didactical relationships that may adapt the learning experience to each learner's personality. The very role of teacher (or facilitator) could in fact be understood as the person who monitors the learning process and supports it in critical events. A student tracking system can from this point of view an important success lever in an educational environment.

In the course *The Institutional and the Society* described above, students were asked to post a synthesis and an evaluation after lecture. On the one side, this helped students to build progressively a set of notes for rehearsal; on the other side, allowed the teaching staff to monitor the level of understanding of the class, possibly to individuate particular cases that could benefit of extra support.

Learning as being in dialogue

---

[3] Observation has been conducted with three instruments: a survey for each lecture (average of students answering: 104 out of 180); semi-structured interviews with a group of 20 students; an open discussion with the whole class at the end of the course.

Learning, as the activity aimed at producing or acquiring knowledge, is essentially a dialogic activity. Establishing a knowledge relationship with an object means being in dialogue with it – once more, the activity is stretched between two poles.

But the creation of a new relationship does not happen in an empty space. All knowledge relationships, form a whole, which is the perceived world of a person's. Among these relationships there are person-to-person relationship, which define the social context. Any creation or modification or re-actualization of a relationship is therefore, at least potentially, a social activity. This is why learning is as well and traditionally the gateway to *belonging to a community*and knowledge the sign of belonging in so many cultures.

Starting from Vygotsky (Vygotsky 1978) collaborative learning research and CSCL have the merit of revealing the importance of the social dimension of learning (Dillenbourg et Al. 1996). This has been often translated into peer-to-peer interaction models, which catch only half of the issue. The fact is that when saying *collaboration*, we should include the teacher/instructor as well: he too collaborates with the learners – he is somehow a learner as well, renewing his/her own knowledge relationship. In the next paragraphs we will focus with more detail on this issue. If the consideration of the educational environment as a whole system (learners-teacher-object-materials) takes the proposed perspective, social interaction in learning acquires a more relevant meaning, passing from being one among several didactical techniques to representing an essential element in learning. This is way any communication system (an online forum, email, meetings) is a critical element in any educational environment.

The learning model proposed above can be a track for planning social interaction at precise step of the cognitive development. Some of the step in the learning dynamic are in fact intrinsically social, while other are strictly dependent on personal engagement. Conceptualization, for instance, can be enhanced by exposition and negotiation of definition; on the other hand, understanding - as getting an insight of a situation - is an individual achievement coming from individual work.

The last two paragraphs have already introduced the relevance of teaching roles in education. On this topic is focused the last part of the paper.

On the Role of Teaching

The most common way for getting in confidence with someone, be it a successful business man that can finance our projects or a beautiful girl that could hopefully marry us, is chatting. The art of chatting is that of finding common interests, of meeting other people on a ground that they can move on with confidence. A known person who introduces us, and suggests us possible conversation topics is a key factor that can increase dramatically our success chances. Chatting can be used for creating the common soft atmosphere of mundane dinners, as well as for getting in confidence with people we can help, such as patients in a hospital or children at school. It is a common way for initiating an eventually stable relationship. The teacher is somehow the person who introduces us to a new knowledge relationship, suggesting interesting and relevant topics, showing us the right communication protocol, providing advice on a favorable language. A teacher is the element that can start the communication flow in the right way. In the beginning, he/she may even embody the dialogical pole the student has to come in touch with, by representing the subject matter in itself, by being directly (or through a medium) in dialogue with students.

But as any professional mediator, the teacher is a time-bound presence, tending to disappear. The more the learner actually learn, the more his/her relationship with the object is stable and strong, the less the teacher is required. Once introduced to each other, the teacher can not require any percentage on the agreement – it was just his/her duty. This ability to introducing pupils to new relationships, and this habit of professional shyness should be the goal of all didactical skills. If we consider higher education, the teacher introduces students not only in a discipline, but in the social environment of a scientific or professional community, acquires.

Out of the metaphor, a teacher - or better, the array of teaching roles configured in any real educational environments: trainer, tutor, coach, media designer, etc. - is the one who consciously controls, anticipates and support the learning dynamic, intervening at different moments with different tools.

This short considerations, which would actually require more space, are the basis upon which we claim that the word *teacher* should not be canceled by the e-learning vocabulary. Of course learning acquires new horizons, but still a relationship can be better and more effectively established if a good teacher provides help. Moreover, several researches show that new media increase the requirements of staff activity and training (teachers, instructors and tutors) in education (Flueckiger & Mazza 2001) (OU 2000).

BEST COPY AVAILABLE

The teacher is a learner

What makes a teacher as such is his/her continuous learning, i.e. the continuous reshaping, adaptation, deepening of his/her personal knowledge relationship with what is being taught. A teacher is lively knowledge in action who invites motivated and interested learners to take part in the movement.

From this perspective lifelong education for teachers is necessary, covering both didactical skills and domain competence. The opportunities offered by e-learning in this domain are therefore appreciable and valuable. This should possibly avoid the trap of simply "being technologically up-to-date": keeping a knowledge relationship lively means much more than that, and means keeping alive motivation (reason and will) and be in touch with a social environment (learning is dialogic) that foster knowledge, a scientific community. We believe that any of our readers will probably have in mind such teachers in his own learning career more than other, maybe didactically skilled teachers.

Conclusions

In this paper we faced some elearning issues starting from very far, going back to one of the roots of Western educational theories, as renewed in more recent authors' work. We did this in the belief that a condition for a successful integration of new media in education is a critical rethinking of education as such, and this can be achieved only renewing our epistemological and pedagogical tradition.

We proposed a conception of knowledge as relationship and tried to show how this approach is scientifically valid and promising for developing a framework for curriculum design and new media in education. We proposed some examples in education theory, education system management and instructional design.

A software tool for developing critical judgments about student writing

This presentation describes the development and design of a software tool designed to assist educators in learning about writing assessment. It also permits back-end data gathering to support research on features of the tool, which include coaching, making judgments and justifying them, and comparing judgments and justifications to those of peers and experts.

The web-based experience, which allows teachers and others to learn about dimensions of writing through rating writing samples and receiving feedback on their ratings, is coordinated with the Nebraska State Writing Assessment. The goal is to help teachers learn to judge dimensions of students' writing and allow them to share their judgments with fellow educators. The project is funded through the Center for Instructional Innovation at the University of Nebraska and NCITE, the National Center for Information Technology in Education.

The project has two complementary dimensions, research and service. The research component is comprised of three related research themes. The first is to test a web-based resource for developing critical judgment and thinking called the ThinkAboutIt! tool. In this tool (1) course content is presented in any of the formats available to Internet delivery (e.g., expository text, narrative text, pictures, video clips, audio clips, etc.). Learners (2) are required to make a choice about how the content should be interpreted or applied. In addition to making a choice, the tool also (3) requires learners to provide a justification or rationale for their choice. When learners have provided their rationales, the tool (4) returns a dynamic graphical display of the frequencies of all choices in the population of learners working on this application. The tool also (5) returns the learner's own rationale and those of all other learners in the population, sorted according to the choices that the learners have made. This permits learners to compare their judgments and rationales to those of their fellow learners. In presenting the rationales, the tool (6) provides learners with the opportunity to interact with the rationales of fellow learners in a variety of ways, including requiring them to select the best rationales, rate a subset of rationales for their quality, e-mail comments to authors of particular rationales, or simply read the rationales. The second research thrust possibility is a study with a sample of students from the Statewide Assessment (March, 2003). Questionnaires and interviews will be used to examine students' experiences with writing and perceptions of writing, efficacy and outcome expectancies for writing, etc. The third research approach will use latent semantic analysis, or a related technique, that compares LSA scoring to the 6-Trait Scoring provided by human scorers of the Nebraska Writing Assessment.

The service dimension involves fulfilling the need to educate the teachers of Nebraska (current and future) on writing assessment. By working with these web-based materials, the teachers will be encouraged to engage more deeply with the content and think critically about the writing samples as they assess them. There are "Coaching", "Expert" and "Peer" functions available within the website. The coaching function is accessed through a "Coaching" button, which provides video, text, or audio coaching in advance of learner judgments to assist them in making informed decisions and forming higher level rationales. The expert judgment function is also accessed by through learners clicking on an "Expert Judgment" button. This function is not available to learners before they make a judgment, but only becomes available after the teachers have made their judgment and provided a rationale. The peer function is also only available after the teachers have made their judgment and provided a rationale and allows for an online discourse on the ratings and judgments for the various student writing samples.

A Framework for Adaptive E-Learning Based on Distributed Re-usable Learning Activities

Abstract: This paper argues that a way to the new generation of powerful E-learning systems starts on the crossroads of two emerging fields: courseware re-use and adaptive educational systems. This paper presents the KnowledgeTree, a framework for adaptive E-learning based on distributed re-usable learning activities that we are currently developing. The goal of KnowledgeTree is to bridge the gap between the information power of modern educational material repositories and the just-in-time delivery and personalization power of ITS and AH technologies.

Introduction

Adaptive Web-based educational systems and standard-based courseware re-use systems constitute two large research and development streams in the field of E-Learning. *Courseware re-use* systems emerged as a reaction to the standard practice of "hardwiring" high-quality educational material items in the course content. This practice made it impossible to reuse educational material and resulted in wasted efforts of the educational community as a whole due to the need to re-develop the same material again and again. The early answer to this problem was a database of educational resources and a courseware-reuse approach to authoring new courses (Olimpo et al., 1990). The courseware reuse ideas has found a fertile ground in Web-enhanced education. Some early large projects in the field of Web-based education like ARIADNE (Forte, Forte & Duval, 1996) and MTS (Graf & Schnaider, 1997) funded by the European Community were centered on courseware reuse. ARIADNE provides a very good example of courseware reuse architecture. It includes multiple *pools* (repositories) of educational material indexed with metadata and an open set of tools to produce, index, and reuse this material. Other well-known European project driven by the same motivation are PROMETEUS (http://www.prometeus.org/) and GESTALT (http://www.fdgroup.com/gestalt/). In the USA the reusability approach has been promoted by EOE Foundation (http://www.eoe.org/) and GEM Consortium (http://www.geminfo.org/).

Adaptive Web-based educational systems (Brusilovsky, 1999) emerged as an alternative to the traditional "one-size-fits-all" approach in the development of educational courseware. These systems build a model of the goals, preferences and knowledge of each individual student, and use this model throughout the interaction with the student in order to adapt to the needs of that student. The first pioneer adaptive Web-based educational systems were developed in 1995-1996 (Brusilovsky, Schwarz & Weber, 1996a; Brusilovsky, Schwarz & Weber, 1996b; De Bra, 1996; Nakabayashi et al., 1995; Okazaki, Watanabe & Kondo, 1996). Since that time, a good number of systems were created all around the world. The majority of adaptive Web-based educational systems are based on technologies developed in the areas of Adaptive Hypermedia (Brusilovsky, 1996) and Intelligent Tutoring Systems (Polson & Richardson, 1988).

The methods and tools developed by the researches on courseware re-use systems and adaptive Web-based educational systems can contribute to creating better Web-enhanced courses. Each of these approaches has strong and weak sides. The courseware re-use frameworks such as ARIADNE allow a course author to search for the relevant learning objects in repositories of educational material and include them in their courses (Figure 1). This approach reduces course development time and improves the quality of courses by making high-quality educational material available for the learning community. At the same time, current implementations of this approach have at least three serious problems.

First of all, modern reusability frameworks implicitly assume that a learning object is a moveable entity - usually a file that is stored in a repository and can be re-used by *copying* into the course to be created. However, advanced re-usable educational objects in modern Web-based education are not files, but activities (services) delivered by a Web server. These activities that can't be simply packaged, stored, and copies as an image, a text file, or even an applet - they have to reside on a dedicated server. This kind of activities is quite typical for adaptive Web-based systems. For example, ELM-ART, an adaptive LISP course (Brusilovsky et al., 1996a) includes many LISP programming problems. Problems are more than just textual problem statements. They are fully interactive learning activities backed by ELM-ART unique knowledge-based functionality. In response to student program solution sent to ELM-ART server, the system can check, diagnose, and correct it. ELM-ART problems can't be moved or copied - they have to be served directly from a dedicated ELM-ART server. There is a clear need to re-use these service-based activities. For example, a teacher may want to re-use ELM-ART problems (based on more than 10 man-year of research) in a very different LISP course. Current re-usability frameworks do not support this.

The second problem is related to the very idea of finding and attaching resources to online course material at the time of course development. The resource repositories are being constantly updated. Some better resources could be added to the existing repositories, some completely new repositories could become available. However, the students can't benefit from these resources due to the static nature of the approach.

The third problem is related to the "one size fits all" problem. When identifying relevant material and organizing it within a course section, the teacher has to think about the class in general. The students in the class have different interests, knowledge, backgrounds, and learning styles. Some material carefully selected by the teacher can be useless for some students and only distract them. Some material that is important for particular students may not even be selected. An organization of material that benefits one category of learners may create obstacles for other categories. This problem is becoming especially important in Web-based education where the variety of learners taking the same course is much greater.

The situation is essentially different in the case of courses produced using adaptive hypermedia (AH) technologies or intelligent tutoring systems (ITS) technologies. Using individual student models and educational material enhanced with domain knowledge, AH and ITS technologies are able to dynamically select the most relevant learning material from their knowledge bases and present it at the right time and in the right way for every individual student, thus making the best use of every fragment of educational material. Educational material in many systems includes "service-style" activities backed by the intelligent capabilities of the system. At the same time, all known ITS and AH systems are build around a "close corpus" material. Collecting and preparing this material for use in adaptive systems is an expensive process. Thus these systems can't directly benefit from existing repositories of learning material.

We believe that a way to the future starts on the crossroads of courseware re-use and adaptive educational systems. This paper presents the KnowledgeTree, a framework for Adaptive E-Learning Based on Distributed Re-usable Learning Activities that we are currently developing. The goal of KnowledgeTree is to bridge the gap between the information power of modern educational material repositories and the just-in-time

BEST COPY AVAILABLE

delivery and personalization power of ITS and AH technologies. The following sections present our vision of the KnowledgeTree framework, review several known problems that it addresses, and describes its most recent version that has already been used in several courses at the University of Pittsburgh.

KnowledgeTree: The Architecture

The KnowledgeTree is a distributed architecture for adaptive E-learning based on re-use of educational activities. It replaces the current monolithic course management systems (CMS) such as Blackbord (Blackboard Inc., 2002) or WebCT (WebCT, 2002) with a community of communicating servers. The architecture anticipates the presence of at least three kinds of servers: activity servers, learning portals, and student model servers (Figure 2). A *learning portal* plays a role similar to modern CMS. It allows a teacher to design a course and manages the student interaction with the course. The difference with CMS is that the learning content (activities) used by the students reside not in the portal, but in multiple distributed *activity servers*. An activity server plays a role similar to an educational repository in the sense that it hosts some (usually specialized) learning content. Unlike repositories that are essentially pools for storing learning materials that can be copied and inserted into courses, an activity server not only stores, but also delivers the activities. A portal has an ability to query activity servers for relevant activities and launch remote activities selected by students. An activity server should be able to inform portals about available activities and provide a complete support for a student working with one of its activities. *Student model server* collects data about student performance from each portal and each activity server that work with a student. In exchange, it provides information about the student that can be used by adaptive activity servers to personalize their communication with the student. The presence of multiple adaptive activities requires a centralized user modeling architecture.

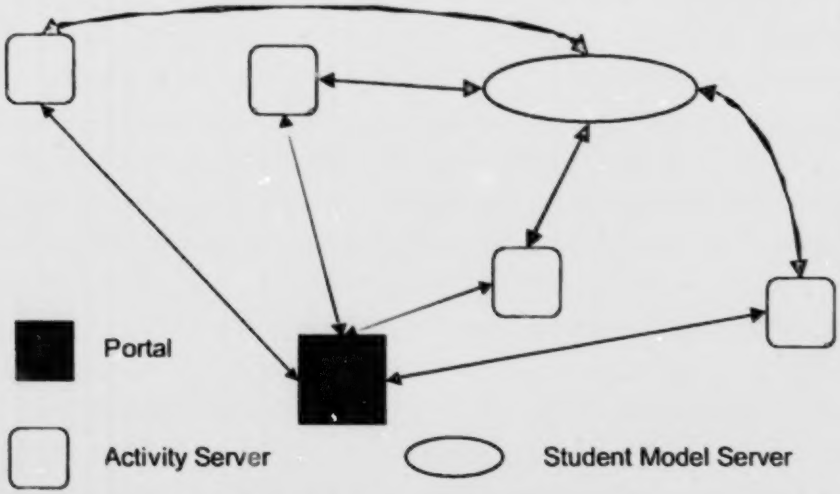

Figure 2: Main components of the KnowledgeTree distributed architecture.

With the KnowledgeTree architecture, a teacher develops a course using one portal and many activity servers. A student works through the portal serving this course, but interacts with many learning activities served directly by various activity servers. The adaptivity is provided by a student model server that collects student performance data from the portal and the activity servers and provides them with integrated information about the student. In particular, a student model server can reside on student's own computer and support just one user. It also can reside on a university computer and support the whole class of students.

The KnowledgeTree architecture is open and flexible. It allows the presence of multiple portals, activity servers, and user modeling servers. The open nature or it allows even small research groups or companies to be "players" in the new E-learning market. An activity server that provides some specific innovative learning activities can be immediately used in multiple courses served by different portals. An innovative portal with a good interface can successfully compete with other portals since it has an access to the same set of resources as other portals. A more powerful student model server can successfully replace older servers.

The open nature of the architecture is based on several clearly defined communication protocols between components. To start with, the architecture needs a protocol for transparent login and authentication. Each adaptive activity should know the identity of the user to use the proper user model, however the student logs in only once. Second, it requires a standard proto[illegible] for a portal to send a query to the activity servers and the standard protocol for the activity servers to respond. Third, it requires a protocol for an activity server to send the information about the student progress to the student model server and a protocol to request information about the student from the student model. Finally, the architecture needs a resource discovery/exchange protocol. A portal can provide an access to a wide variety of learning activities residing on many servers. However, to benefit from this feature, a portal should know about many servers and kinds of activities they can offer.

The current version of KnowledgeTree provides offers very simple implementation of the first three protocols. Every activity us called directly by a dedicated URL. The transparent authentication is implemented by passing a session and a student identifiers as a part of activity URL. We use a rather simple http-based communication language between components, similar to the one we have developed in our past research on distributed intelligent tutoring (Brusilovsky, Ritter & Schwarz, 1997). While these protocols offer some solution that enables us to work and explore the distributed architecture, they are clearly "homegrown". More research is requited to develop protocols that can be commonly acceptable.

The resource discovery issue has not been addressed in the current version of KnowlegdeTree. Currently, we simply "tell" the portal about all existing activity servers. In the open context none of the portals can know all relevant activity servers and there is no centralized authority to collect this information. This requires a "resource propagation" mechanism for various portals to exchange information (metadata) about known servers and activities.

KnowledgeTree: The Portal

The KnowledgeTree architecture allows multiple portals that can support different educational paradigms and approaches. At the moment, we have implemented one portal also called KnowledgeTree that is targeted to support a lecture-based educational process and is focussed on dynamic and adaptive selection of learning activities.

Main users of any portal are course authors (teachers) and learners. Course authors are responsible for shaping a course as a structured container of educational activities. The KnowledgeTree model allows an author to develop a course as a tree of modules (note that a sequence is also supported since it is a a one-level tree). While for most authors a module will correspond to a lecture, an author has a freedom to define larger modules that comprise several lectures as well as smaller-size modules. The course can also be structured independently from a sequence of lectures – as an interactive electronic book. In any case, the role of the author here is to structure the set of modules and to select primary educational material for each module. We distinguish primary material that comprises minimal set of activities necessary for an average student to learn the module and additional material that enhances learning experience and provides relevant activities for the students with different learning styles and levels of knowledge.

To select the material for each section an author specifies an educational goal for a section. The specification can be done in both natural language and in a formal language that expresses the goal in terms of metadata associated with necessary learning activities. During the course design process, the educational goal is used by the system to select subset of relevant educational activities from multiple learning repositories known to the system. The selection can be done using a formal query to metadata-backed repositories or using a fuzzy text-based matching for repositories that have no metadata. From this pre-selected subset of activities an author can simply manually select most relevant primary and additional learning activities. To complement the set of activities found in the repositories, some activities can be designed by the author.

The above process is quite similar to the process supported by advanced courseware re-use tools. New feature of the KnowledgeTree model is that the learning goal specified by the author is retained and stored with the module. When a particular student accesses the module during educational process, the *learning portal* uses this learning goal as well as the student model to select adaptively most relevant additional material for the given student *at the runtime*. Adaptive runtime selection allows the system to accommodate to the volatile and expanding nature of learning repositories and to student individual differences (Figure 3).

It is easy to anticipate that in the future, when learning repositories will be quite rich, the runtime selection will return a relatively large number of relevant learning activities. In this context, adaptive hypermedia technologies will provide further adaptation for an individual student. Adaptive navigation support (such as adaptive annotation, sorting, and direct guidance) will be used to help the student to select the currently most relevant items in the personalized learning space. Here the system will adapt to student knowledge and individual learning styles. Adaptive presentation will be used to deliver selected items adaptively. Here the system will adapt to the student level of knowledge and educational goal. In addition, the system also allows the student to search for relevant educational material using her own criteria and to add material permanently to the module. It produces a dynamic and personalized learning space for each course module where personalization is provided by both the system and the student (Figure 3).

Figure 3: KnowledgeTree portal combines the benefits of courseware re-use systems and adaptive Web-based educational systems. It solves the problem of statically built courses, and provides personalized support that maximizes an educational opportunity for every learner.

The above scheme presents the most generic case of the system use. The system naturally supports any subset of the underlined functions. For example, the author may specify a partial educational goal and choose not to select any primary educational material. In that case, the system still will be able to use a partial goal to select and organized relevant educational material for every section. Thus, with little efforts from the author the system will be able to provide an impressive level of adaptive support.

Current State of Work

In addition to the overall architecture, a set of protocols, and the KnowledgeTree portal, the list of components developed so far includes four protocol-compliant activity servers and a simple user modeling server. Three of these activity servers have been developed for the area of teaching programming. Each server supports authoring of a specific kind of activity and supports student's interaction with a selected activity of this kind. The WebEx system (Brusilovsky, 2001) serves interactive annotated program examples, the QuizPACK (Pathak & Brusilovsky, 2002) serves parameterized questions, and WADEIn (Brusilovsky & Su, 2002) serves demonstrations and exercises related with expression evaluation. The fourth server KnowledgeSea (Brusilovsky & Rizzo, 2002) is domain independent, and currently used to provide an interactive access to open corpus learning material. All activity servers are self-containing Web servers running on different

BEST COPY AVAILABLE

platforms and completely independent from a portal. WebEx is implemented using Microsoft ASP technology and served by Internet Information Server (IIS) working on a Windows PC. QuizPACK is developed as a set of C++ CGI scripts and is served by Apache server working on a SUN Solaris platform. WADEIn is implemented as a configurable Java applet embedded into a page generated by a Java servlet running on a Tomcat server. KnowledgeSea is based on JavaScript functionality and can be delivered by any Web server. Each server can work independently from the KnowledgeTree architecture, but will require a student to login in this mode of work. Only one of the activity servers (WADEIn) serves adaptive activities. It use the information about students to adapt to their knowledge. Other servers use information about the student simply to trace the student performance. All these servers implement our simple transparent login protocol, resource delivery protocol, and student modeling protocol. They can work (with transparent login) with any compliant portal and user modeling server.

Figure 4: A module view in a second version of KnowledgeTree portal. The learning activities in Examples and Quiz categories are delivered by external activity servers WADEIn, WebEx, and QuizPACK.

The first version of the KnowledgeTree portal together with WebEx and QuizPACK servers and a primitive student model server was piloted in the Fall 2001 semester in the context of a programming and data structure course. In Spring 2002 semester the version 1.5 of the portal (Figure 4) and all four activity servers were used as a primary course support tool in the context of another programming course. Many activities created for the first course were re-used in the second course and we have appreciated ourselves how easy was it to assemble a course from re-used activities. The students were using the system and its components on everyday basis. All components of the system were formally evaluated and got very positive feedback from the students.

Currently we are completing the second version of the portal. Following the earlier versions, it is implemented using Java Servlet and JDBC technologies and delivered by Tomcat server. It supports hierarchical course design (first version supported sequences only), specification of educational objectives of a module in terms of course concepts/topics. It is able to retrieve external learning activities that matches the educational objectives of the module. The second version also supports multiple course authors and groups. We are also developing the second version of the student model server. The second version implements in full the centralized user modeling approach developed in our earlier research. (Brusilovsky, 1994; Brusilovsky, 1995). This version is based on Java Servlet and JDBC and will replace the current simple user model server that is based on Microsoft ASP technology.

We expect that in the Fall 2002 semester several faculty will be using the KnowledgeTree in the context of their courses. The readers are welcome to try the current version of the system available from our lab home pages: http://www2.sis.pitt.edu/~peterb/taler.html.

Other Relevant Research and the Prospects for the Distributed Framework

Significant amount of work and cooperation of several research groups is required to turn the proposed framework into the practice of e-learning. We have started with implementing the core functionality of the system within our local group using some rather simple ways to implement the required protocols. However, any open architecture has to be based on a number of standards. Fortunately, our work shares some core goals with several other active research areas. Instead of inventing the solution we intend to re-use as much as possible standards, solutions and ideas from these area.

- The problem of searching for relevant educational activities in learning repositories is now well explored by courseware re-use movement and Learning Object Metadata groups (such as LTSC http://ltsc.ieee.org) in particular. Solutions developed within this field can be directly adopted by our framework
- A good variety of powerful adaptation methods and techniques have been explored in the field of adaptive Web-based educational systems. This field is our primary source of ideas for developing both the portals and the adaptive activities.
- Several consortia such as uPortal (http://www.uportal.org) and AICC (http://www.aicc.org) explore the issues of distributed component-based architectures for E-learning as an alternative to monolithic courseware management systems. These groups have already produced some solutions for transparent authentication and communication standards between a portal and an "intelligent" learning activity.
- The problem of gathering and sharing metadata of distributed resources has been carefully investigated in the field of Web information retrieval. Some interesting centralized architectures as FAB (Balabanovic & Shoham, 1997) and decentralized architectures as Harvest were suggested. These ideas can be certainly re-used for the needs of E-learning. In the context of e-learning EDUTELLA (http://edutella.jxta.org/) and LOMster (Ternier, Duval & Vandepitte, 2002) projects develop frameworks for peer-to-peer metadata exchange.
- The issue of user and student modeling for multi-component adaptive systems has been well-researched in the fields of ITS and User Modeling. A number of user and student model servers have been already reported (Kobsa, 2001). These works can certainly contribute to the development of the user model component of KnowledgeTree framework. The AICC CMI standard can also contribute to this aspect of our framework since it suggest a way for an "activity" to report the results of student work with it.

We should conclude by mentioning that the problems of developing distributed adaptive and intelligent educational system based on shared educational resources has also been explored in the field of ITS (Brusilovsky, 1995; Brusilovsky et al., 1997; Eliot, Woolf & Lesser, 2001; Murray, 1998; Ritter, Brusilovsky & Medvedeva, 1998; Ritter & Koedinger, 1996). However, the lack of matching works in other fields and the proper technology in general didn't allow these pioneer works to go beyond the level of ideas and simple lab systems. The current situation is quite different. Not only we can now use some matching solutions from the areas listed above, the Web in general now provide a powerful platform for implementation of the long discussed ideas. The race for e-commerce, enterprise systems, Web services, personalization, brought to life many technologies that can be used for development of adaptive distributed E-learning. We hope that our group together with other groups motivated by similar goals will be able will now succeed in bringing our a new generation of E-learning systems that integrates best features of several emerging systems.

Abstract

This report describes a research project designed to investigate the relationship between perceived organizational culture and the current general level of Internet self-efficacy as well as with two sub-categories of expertise: use of course management shell software and Web authoring software. The perceived organizational dimension of "employee focus" was positively correlated with the three technology measures whereas the perceived organizational dimension of "results focus" was negatively correlated with these three measures. Although the findings are mitigated due to the small sample size, they do correspond with a general perception within academic institutions that staff are more likely to be innovative when there is support for their efforts than when there is simply pressure to produce. Overall, the findings of this research project suggest that organizations moving online need to be cognizant of the effect of different organizational climates on their staff and should take this into account when planning their change management strategies.

Introduction

There is a burgeoning literature on topics related to the integration of Information Technology (IT) within organizations. Two disciplines that have shown a particularly strong interest in this topic are Business and Education. The impact of these technological developments on institutions is putting increasing stress on almost all aspects of their operation (Isaacs, 1999; McMurray, 2001). In many cases it seems to require a complete rethinking of an organization's goals and functions. In some cases it may recommend a complete reorganization of an institution or company. In other cases the change may be less dramatic but still important. This appears to be the case within educational institutions, where the core purpose of the institution appears to remain relatively intact, but where there are new opportunities for how we may best provide a dynamic and relevant environment for our students. Wallace (1999) has provided a timely review on various psychological issues related to the use of the Internet. At the same time there must be increasing attention placed on some of the difficulties of developing online instruction. Factors such as reliable technology, support for faculty, and the familiarity of the system among students are commonly mentioned (Auter, P. J. & Hanna, M. S., 1996; Rogers, C. S. & Laws, P., 1996).

Background

The business literature consistently emphasizes the importance of the organizational culture in understanding a corporation's effectiveness. The ideas appear to apply equally well to any large organization, including that of a university. Quinn and Rohrbaugh (1983), Quinn et al. (1996) have developed a theoretical model for describing such a culture, called the Competing Values Framework (CVF), sometimes also referred to as the Competing Values Model (CVM). The model was originally derived empirically from multivariate analysis of response data. Howard (1998) has recently provided an important psychometric validation of this model. Dastmalchian (1999) has broadened the idea to provide a

BEST COPY AVAILABLE

comparison of perceived emphasis with desired emphasis and although the model was originally designed to describe business organizations, Barath (1998) has extended the sphere of application to that of school jurisdictions.

Basically the CVF postulates a three-dimensional bipolar model for organizational culture. The three dimensions are labelled (control & stability)/flexibility, internal/external focus and means/end emphasis. Each of these three dimensions is considered to be orthogonal to the others. The model is sometimes simplified to incorporate just the first two-dimensions (Dastmalchian, 1999). These two dimensions divide the organizational culture into four quadrants, each representing a set of core values (Figure 1).

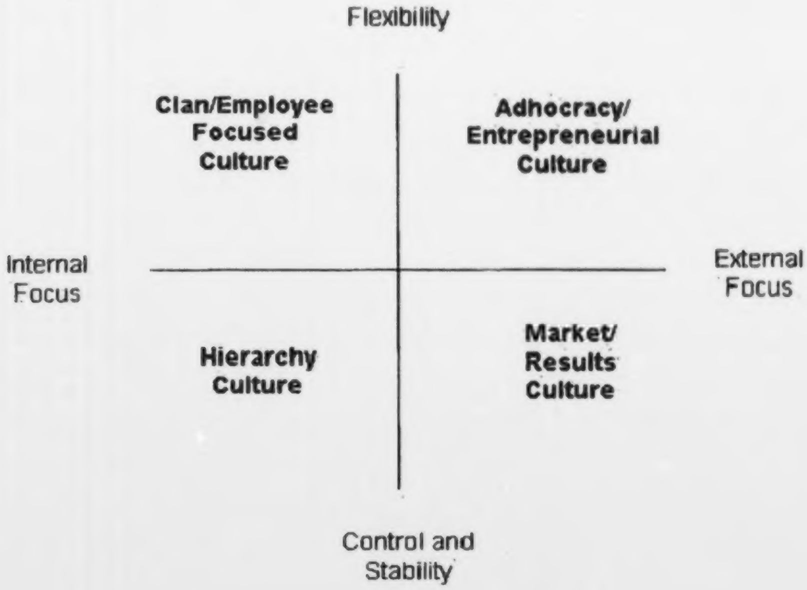

Figure 1 Perceived Organizational Cultures

Usually this model is then used as a framework for plotting the institutional profile, obtained by averaging the data from the individuals responding to the study. However in the present case, it was decided to treat each individual profile on its own, and examine how well that profile corresponds to data obtained on Internet self-efficacy. It is worth noting that the measure for each quadrant is based on the "perceived" emphasis of that characteristic by a respondent within the culture, rather than as some form of judgement about the culture by an external assessment.

Data Collection

The approach taken in this project was to create two survey instruments, based on the available research literature on organizational culture and on computer self-efficacy, and administer this to the staff of a small university. In addition to a series of Likert scale items, a number of open-ended questions were added that asked the respondent to comment of their present activities and future plans within the context of preparing for online instructional materials. The present report presents an analysis of the CVF questionnaire and the Likert items from the Internet questionnaire.

Sampling

The original sample involved two organizational departments. Participation in the study was voluntary. A total of 16 people were approached in one department and 12 in the other. Of these 28 potential respondents, a total of 16 (57%) filled in at least one of the two survey forms. The study was not designed to compare departmentss, but to examine individual profiles, so all of the data were either analyzed at an individual level or were combined for a global analysis. Notices were sent to other departments, informing them of the research project and inviting their participation. This resulted in an additional 6 subjects responding from 4 different departments.

Instruments

The first questionnaire, based on the concept of Internet self-efficacy, was designed specifically for this study. Many of the items were originally used in previous research studies (Eastin & LaRose, 2000; Kelley, Higgins and Compeau, 1999), but were some items modified to provide information directly related to the use of the Internet and the development of online instructional materials. The second questionnaire was obtained from Dastmalchian (1999) and was used without modification. An online version of each questionnaire was also developed and everyone was given the option of using either the hardcopy or online version. The online version was completed by 16 respondents whereas 6 selected the hardcopy form.

The organizational culture exercise asked respondents to distribute 100 "points" across 4 descriptions of hypothetical organizations, depending on how close each description was to their perceived situation. For example, if a subject felt that the university was very much like this description: "Organization A is a very personal place. It is like an extended family. People seem to share a lot of themselves", then they would allocate most of the 100 points to that description. Similar descriptions were provided for organizational cultures similar to the other three quadrants of the CVF. This exercise was repeated a total of 6 times with different aspects of the organization (e.g. Dominant Characteristics, Organizational Leader, Organizational Glue, Organizational Climate, Criteria of Success, and Management Style) being profiled. The scores for each of the four organizational climates were then totalled. Thus, a total of 600 points were distributed over 4 organizational climates, with the average value being 150 if all four climates were rated as equally valid.

The Internet questionnaire contained two sets of questions that asked respondents to indicate on a 7-point scale the degree of experience they had with various course management shell programs (e.g. Learning Space, BlackBoard, WebCT) and with different Web authoring tools (e.g. FrontPage, HomePage, Dreamweaver, GoLive, Fusion). In addition a 17 item (each item a 7-point scale) Internet self-efficacy instrument was included in the questionnaire. Average ratings for each subject on each of these three scales were computed.

Analysis

The small sample size ruled out the use of inferential statistics, however there is merit in reviewing the descriptive statistics. Correlations were computed for each of the four competing value framework dimensions with the three indices of Internet experience (Figure 2).

	Shell Management	Web Authoring	Internet Self-efficacy
Clan/Employee	0.43	0.08	0.41
Adhocracy/Entrepreneurial	-0.03	-0.05	0.05
Hierarchy	0.02	0.18	-0.10
Market/Results	-0.45	-0.22	-0.32

Figure 2 Correlation Matrix of CVF Scores With Internet Experience

The correlation between the perception of an Employee Focused Culture and course management shell experience (Learning Space, BlackBoard, WebCT) was 0.43. Similarly, the correlation between a perceived Results Culture and this same experiential dimension was -0.45. The remaining two organizational culture dimensions did not exhibit large correlations with the experiential variables. Thus the principal finding of the research project was the indication of a strong positive relationship between a perception of being in an

Clan/Employee Focus Culture and having learned to use course management shell software, whereas there was an equally strong negative relationship between a perception of being in a Market/Results Culture and this experiential dimension.

Figures 3 and 4 show the radar graphs for two individuals with high scores on either perceived "Clan/Employee Focus Culture" or "Results Focus Culture". These are both fairly typical of the graphs for people scoring high on these two dimensions. Note that these diagrams emphasize the value for each of the four CVF quadrants, rather than values for the bipolar dimensions outlined in Figure 1. That is, 1 = Clan/Employee Focused Culture; 2 = Adhocracy/Etrepreneurial Culture; 3 = Market/Results Culture; 4 = Hierarchy Culture.

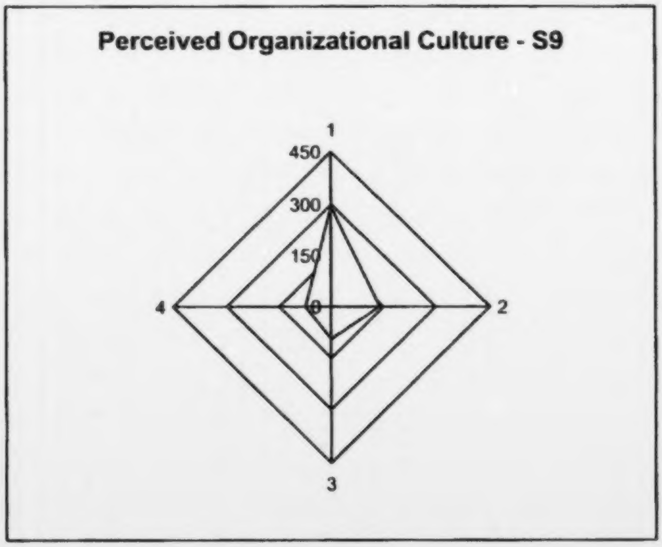

Figure 3

In addition to observing that the highest value is for dimension 1, it is worth noting that values for dimensions 2, 3 and 4 are all under 150. The instrument produces an ipsative measure, which means that, in this case, a total of 600 points were distributed among the four dimensions. An allocation of a large number of points to one dimension results in fewer points available for distribution among the remaining dimensions. If all four dimensions were to receive the same weighting, then all scores would be 150. In the case of Subject 9, the Clan/Employee Focus dimension has a weighting of almost 300 and all of the remaining three dimensions have values less than 150. Recall that the computing of the three scales related to Internet expertise was simply the average rating of a number of 7 point Likert questions. This individual indicated an average score of 6.7 for experience with course management shell software, 4.0 for experience with web authoring software, and 6.6 on the Internet self-efficacy variable. The latter two scores were the highest scores among the group that replied to the survey. This is consistent with the correlations, namely a high score on "Clan/Employee Focused Culture" and a low score on "Market/Results Culture" both correspond to a high scores on experience with course management shell software, experience with web authoring software and Internet self-efficacy.

BEST COPY AVAILABLE

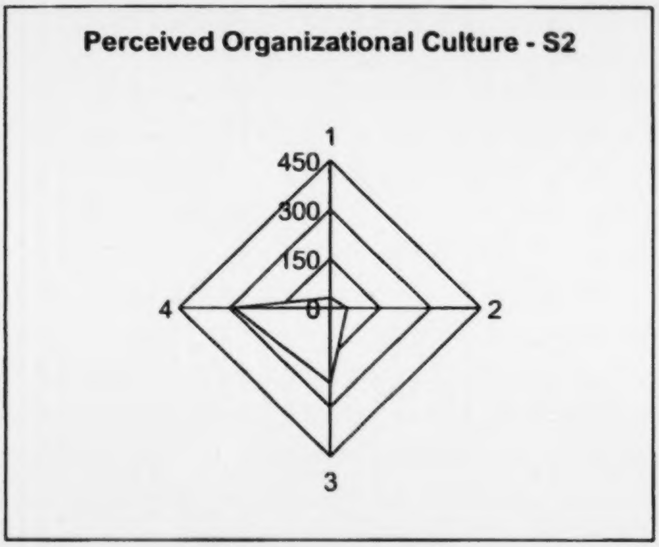

Figure 4

The graph in Figure 4 is also typical of those for people who gave the highest value to dimension 4 – a perception that the organizational climate has a "Results Focus". In this case, the third dimension, "Hierarchical Structure" also tended to receive a fairly high score. This individual had an average score of 0.67 for experience with course management shell software, 0 for experience with web authoring software, and an average score of 4.5 (out of 7) on an Internet self-efficacy variable, which was below the overall average for the group that replied to the survey. That is, a high score on "Results Focus" corresponds to low scores on the three Internet related variables.

Discussion and Conclusions

The results are suggestive of a strong relationship between perceived organizational climate and involvement in utilizing the Internet. Both a general index of Internet self-efficacy as well as two measures of experience with Web support software were shown to be related to this organizational climate, with the dimension of "Employee Focused" being positively related to use of the Internet and the dimension of "Results Focused" being negatively related to use of the Internet. While much attention has been given to specific support strategies to aid in helping faculty become more involved with e-learning, one should not lose site of the impact of the overall perceived organizational climate as a contributing factor to the incorporation of Internet related activities in instructional activities. In general, it appears that an organizational climate that is "Employee Focused" is more likely to result in activities that involve innovation and exploration, such as the learning of new Web-related skills. Keeping in mind that the entire field of Web-based educational courseware development and delivery is presently in a state of rapid evolution, such a supportive organizational climate is important for staff members to continue to play with new ideas that will eventually impact on the overall effectiveness of the institution.

Distance Education Quality:
The Resources—Practices—Results Cycle and the Standards

Dr. Cathy Cavanaugh, Curriculum and Instruction, University of North Florida, USA. ccavanau@unf.edu

Abstract: The development and implementation of effective distance education happens in an iterative cycle. The three stages in the cycle are (1) procurement and preparation of the resources necessary to meet the distance education goals, (2) delivery of instruction using the best practices from education, business and research, and (3) analysis of the results of distance education to gauge achievement of the goals. Each stage of the Resources–Practices–Results (RPR) cycle continually revisits lessons learned in the other stages and builds upon the successes realized in the other stages. This paper explores the match among the established success factors incorporated into the RPR cycle and six sets of distance education standards published by higher education boards and councils in the UK and in the US at national and regional levels. There is variation in the degree to which the standards address the RPR success factors.

Defining Quality

In its December 2000 report to Congress, the Web-Based Education Commission made high quality online educational content one of its seven critical issues. In order for a student or institution to determine whether quality has been achieved, quality must be defined. Primarily, distance education programs must serve institutions in meeting their goals. A central goal of education is developing independent learners who can capably apply their knowledge to new situations. To ensure that distance education offerings meet this goal, providers must identify desired learning outcomes and instructional methods. Quality indicates that instruction is effective and appropriate. The definition of quality may include quantitative elements such as completion rates, student performance, and student evaluations of the learning experience. Qualitative dimensions may include ratings of teaching-learning events, materials, learning process, pace, activities, content and options offered to students. Several higher education accrediting and policy groups have recently released distance learning standards as guides toward quality improvement.

The Quality Distance Education Cycle

The process of developing and implementing effective distance education happens in an iterative cycle. Broadly considered, the three stages in the cycle are (1) procurement and preparation of the resources necessary to meet the distance education goals, (2) delivery of instruction using the best practices from education, business and research, and (3) analysis of the results of distance education to gauge achievement of the goals. Each stage of the **Resources–Practices–Results (RPR)** cycle continually revisits lessons learned in the other stages and builds upon the successes realized in the other stages (Cavanaugh 2002). Each stage requires participation of all stakeholders, including students, instructors, support and design professionals, administrators, and the community. The success factors included in each stage are based on decades of research and experience with learners from professions, higher education and K-12 education (Barker, 1999; Bruce, Fallon & Horton, 2000; Cavanaugh, 1999; Educational Development Associates, 1998; Fredericksen, E., Peltz, W. & Swan, K., 2000; Institute for Higher Education Policy, 2000; Mantyla, 1999).

This paper explores the match among the established success factors incorporated into the RPR cycle and the distance education standards published by higher education boards and councils.

The Resources Phase of the RPR Cycle

The resources required to sustain a quality distance education program exist to support students, faculty, and the program or institution toward achieving the goal of effective and appropriate learning. Responsive and flexible human resources, knowledge, skills, policies, procedures and technical infrastructure enable quality practices and contribute to quality results. Procurement, development and adaptation of resources are ongoing processes.

Success factors for the Resources phase:

- Institutional policy that values distance education
- Strategic plan for delivering distance education to students
- Stakeholder analysis to determine needs of graduates
- Financial commitment that gives the direction regarding program implementation
- Team support for distance educators and students
- Appropriate technology infrastructure
- Program standards to guide course design and delivery
- Program review to ensure that all components of the program meet standards and to ensure that the standards contribute to program goals
- Effective communication of policies and expectations to students
- Student services: information, advising, orientation, and security
- Information privacy
- Qualified, experienced staff and faculty
- Community involvement in the program's goals, policies, and outcomes
- Information provided to faculty about teaching in the distance learning environment
- Instructor release time for course development
- Instructor training in distance education pedagogy and technology
- Course design and delivery assistance
- Well-designed and appropriate learning materials
- Student orientation and training
- Student access to learning resources and instructors
- Technical support for instructors and students
- Technology plan to communicate goals to all users

The Practices Phase of the RPR Cycle

With the right resources in place, the stage is set for dramatic distance learning performance. At this point the spotlight shifts from the institution to the instructor. Quality distance teaching begins with the careful design of courses, materials and learning activities. Next, the instructional practices employed during instruction will aim at developing independent learners with the ability to transfer their learning to novel situations. Throughout the course, effective communication and community building are essential foundations for all events.

Success factors for the Practices phase:

- Focus on content and students
- Relevant and important skills and knowledge addressed in courses
- Structured information presented in motivating context
- Social strategies to promote student comfort, control, challenge
- Fast feedback from instructors to students
- Consistent design throughout each course
- Highly interactive activities for student engagement

BEST COPY AVAILABLE

- Authentic communication among students, instructors and experts
- Course activities designed to maximize student motivation
- Activities focused on high-level cognitive skills
- Development of information literacy
- Development of applied technical skills

The Results Phase of the RPR Cycle

The only way to know whether a distance education program has achieved quality is to compare the program results to established quality benchmarks. Measures of quality are tied to institutional goals, and account for the specific context of the program. To maintain success, a distance education program evaluation must account for institutional and instructional factors as well as student factors. Evaluation of course and program results is a continual process that involves all stakeholders and requires a wide range of tools. Success is evaluated by through assessment of student learning, program review, and program accreditation.

Success factors for the Results phase:

- Student independence developed through opportunities for self-assessment
- Peer review of student work as a professional experience
- Creation of student portfolios to showcase accomplishments
- Varied assessments for an accurate view of student abilities
- Open-ended assignments to increase thinking skills and reduce cheating
- Secure online testing
- Ongoing course evaluation by students
- Evaluation of program by students and faculty
- Review of program outcomes and components by all stakeholders
- Program accreditation

Standards

Worldwide, organizations with an interest in distance education have published standards to guide institutions and instructors in delivering quality courses and programs. Standards have been developed by regional and national higher education accrediting bodies, by national education labor unions, and by national councils concerned with higher education and distance learning.

Title of standards document	**Agencies**	**RPR success factors addressed**	**Web address**
Distance Learning Guidelines	The Quality Assurance Agency for Higher Education. UK	10	http://www.qaa.ac.uk
Standards in Open and Distance Learning	Open and Distance Learning Council. UK	10	http://www.odlqc.org.uk
Distance Education Guidelines for Good Practice	Higher Education Program and Policy Council of the American Federation of Teachers. US	16	http://www.aft.org

Evaluation of Distance Learning Programs	National Council for Accreditation of Teacher Education	14	http://www.ncate.org
Principles of Good Practice	Southern Regional Education Board. US	17	http://www.electroniccampus.org
Distance Education: Definition and Principles	The Commission on Colleges Southern Association of Colleges and Schools. US	19	http://www.sacscoc.org

Table 1: Standards used in this analysis

The *Distance Learning Guidelines* of The Quality Assurance Agency for Higher Education in the UK "offer advice on assuring the quality and academic standards of higher education programmes of study provided through distance learning" and "are concerned with arrangements made by UK universities and colleges to provide programmes of study by means of distance learning" (QAAHE 2002). The standards will be reviewed and become the starting point for a code of practice for distance learning.

> The guidelines have been produced at the request of the distance learning community in the United Kingdom, which has recognised not only that the continued development of this form of higher education and its worldwide acceptance depend upon rigorous quality assurance, but also that there are many areas in which the usual ways of doing things for 'on-campus' provision are not necessarily appropriate in the context of distance learning (QAAHE 2002).

The Open and Distance Learning Council of the UK developed *the Standards in Open and Distance Learning* to apply across the range of open and distance learning. The Council accredits ODL programs meeting the standards, and acts as a clearinghouse of information on ODL providers for students. An independent body, the Council was set up at the request of government to enhance quality in education and training, and "to protect the interests of learners, through the accreditation of open and distance learning providers. Accreditation includes a rigorous assessment of a college's administrative and tutorial methods, educational materials and publicity. Accredited colleges are monitored to ensure that students continue to receive good service, and are re-assessed at least once every three years." (ODLC 2002)

The Higher Education Program and Policy Council of the American Federation of Teachers (AFT) in the US created the *Distance Education Guidelines for Good Practice*. The AFT, a labor union, developed the guidelines from distance learning literature and from surveys of distance educators. A goal of the standards project was to specify in detail practices found to be effective. The guidelines were published to "assist faculty members teaching, or preparing to teach, distance education courses, as well as higher education locals negotiating distance education issues with management" (AFT 2000). The guidelines are also designed to serve "college administrators and public officials who want to put quality at the center of their technology programs, as well as other organizations around the country" (AFT2000). The primary focus of the standards is the college credit-bearing two-year, four-year and graduate program.

The National Council for Accreditation of Teacher Education (NCATE) in the US released the *Evaluation of Distance Learning Programs* as a guide for evaluators of teacher preparation programs. Distance learning components are subject to the same standards as other components of accredited teacher preparation programs.

The Southern Regional Educational Board (SREB) in the US helps students find in high-quality courses and programs at colleges and universities in the SREB region. The *Principles of Good Practice* "were developed to assure students about the quality of courses and programs at the Electronic Campus. The principles draw upon the work of the Western Interstate Commission for Higher Education and other organizations. All courses and programs to be listed in the Electronic Campus have been reviewed against the Principles of Good Practice by the offering colleges or universities and have been coordinated through the state higher education agency" (SREB 2001).

The Commission on Colleges Southern Association of Colleges and Schools is the recognized regional accrediting body in the eleven U.S. Southern states and Latin America for institutions of higher education. "In order to facilitate the evaluation of distance education throughout the United States, the regional accrediting associations have agreed upon the following definition and principles. This agreement is based on an extension of the Principles developed by the Western Interstate Commission on Higher Education" (SACS 2000).

The success factors of the RPR cycle include practices at the instruction, program, and instructor levels. Because of the varying foci of the groups producing distance education standards, there is variation in the degree to which each set of standards matches the RPR success factors. The two sets of UK standards addressed the fewest (10 each) of the 44 success factors, with the matches occurring in the areas of program policy and review, accreditation, student evaluation and support, and developing student skills. The two sets of standards developed by national agencies in the US addressed many more (14 and 16) of the success factors. The factors addressed by the US national standards included student and instructor support, program planning and review, instructor qualifications, course interactivity and student assessment. The two sets of standards created by regional agencies in the US addressed the highest number of success factors (17 and 19). Areas covered include student and instructor support, program planning and review, instructor qualifications, course interactivity, student assessment, learning materials, and information privacy.

Only 13 of 44 success factors were not specifically addressed by any of the reviewed standards documents. Factors not mentioned in the standards related to involvement of community members or stakeholders in course or program review processes, and to specific teaching strategies found to be effective in distance education, such as motivation-building, teamwork, peer review, portfolio assessment, open-ended assignments, and social strategies leading to student success.

Together, the UK, US and regional distance education standards reviewed addressed the majority of the success factors identified in the literature and practice of distance education. The standards should be considered valuable guidelines, but not complete instruction manuals for distance education providers. Providers are encouraged to continue to review the literature to add their own standards of practice to the standards provided by outside agencies.

Conclusion

With the worldwide number of Internet users expected to reach 1 billion by 2005 (Computer Industry Almanac, 2002), and the increasingly frequent need for employees to update their knowledge and skills to adapt to the rapidly changing workplace, interest in distance education will continue to grow. In response, distance education offerings will grow, and competition for students will grow. Students online have access to any online course, and the tools of the web allow students to quickly compare courses. A strength of distance education is its potential to focus the learning process on the student. Courses and programs that emphasize their focus on the student's strengths and needs will succeed in attracting students. In order to build their reputations and keep students, courses and programs must reach quality goals. High-quality distance education achievement is the outcome of the dedication of all constituents in the continual quest for the best possible resources, practices and results. With increased need for new career skills and improvement in delivery technology, distance education students will demand evidence of quality and authenticity in distance courses. It is imperative that distance education providers implement and review quality benchmarks regarding Resources-Practices-Results in response to the needs of students, employers and the community. Educational institutions must continue to develop and maintain standards, and they must clearly communicate those standards to the public. When students benefit from an education program that meets their needs, the community benefits as well.

Thinking Outside the Circle: the Design of Face-to-Face Collaborative Learning Facilities

Robert W. Cavenagh
Director of Instructional Technology
Dickinson College
Carlisle, PA 17013, USA
cavenagh@dickinson.edu
http://dickinson.edu/~cavenagh

Abstract: Learners working on collaborative assignments in a face-to-face environment while using computers must engage in social as well as intellectual tasks. Indeed, at the residential undergraduate level, the development of interactive skills is often one of the more important aspects of their collaboration. Many existing facilities support such interaction badly if at all. This writer has undertaken a continuing investigation of persons-computer-facility interaction and has developed a series of learning facilities that appear to strengthen the quality of learner interaction by increasing time on tasks. This report demonstrates the process of creating groupwork oriented class and study spaces, the challenges and variables encountered, and the first pedagogical results of this work-in-progress. It also explores pedagogical issues and strategies for instructors using such arrangements.

Overview:

This paper is about fostering collaboration, and in particular about fostering collaboration among learners who work together in face-to-face environments and use computers. In practice such learners also tend to use computer tools on their own: e-mail, online learning environments such as Blackboard and WebCT, the web itself, PowerPoint, and a variety of other options. Collaboration can take place in a classroom with an instructor, in other learning spaces with an instructor, and in a variety of settings without an instructor present.

The use of collaboration to prompt learner interaction has been much noted in the educational literature. Learners in interactive groups are more likely to play active than passive roles. The participative nature of such learning experiences can lead to social reinforcement for participation from other group members; the negotiations required in interactive activities are also useful in modeling other forms of social interaction, such as occur in many workplaces. Such results are not automatic, however, and faculty need to understand how to nurture these processes.

The rise of useful computer technologies in the last decade---tools such as the World Wide Web or PowerPoint, and (more recently) video editing---and the increasing availability of such technologies in schools, colleges and universities, make these things seem ready-made for collaborative learning activities. Many faculty create assignments requiring groups to use such tools for research or for reporting.

Unfortunately, the actual use of technology by groups can occasion some difficulties. Most computer installations are designed for single users and are not easily shared by groups. When more than two learners attempt using such facilities, one or more tend to hold back, to be passive, to observe at some distance. This is not useful in facilitating the group goals.

I first encountered these problems while teaching classes in Instructional Technology and observed students assuming uncomfortable postures while trying to share a screen with a group. This led in turn to an iterative process of observation, experimentation, and the development of learning facilities and pedagogical procedures.

This paper will recount the paths taken, and will provide a preliminary report on the latest steps, classrooms specifically designed for group work at computers. It will also consider the issues involved in teaching and learning in such environments. You will find updated information at the listed website.

Background:

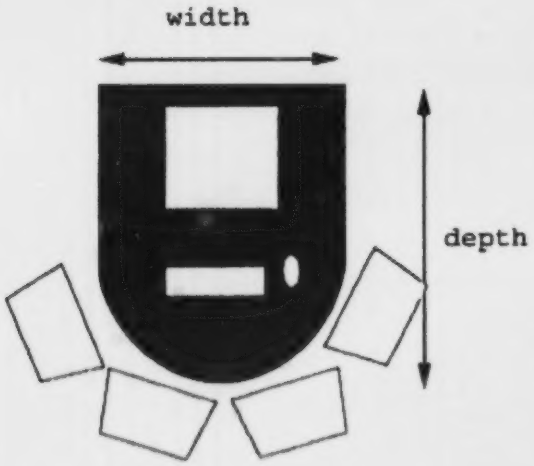
In 1992 I first observed that students who attempted to share a computing task encountered a series of physical barriers. Computer labs were routinely organized in rows, monitors were just large enough for a single user, and the close spacing of computers precluded more than a pair of students sharing a screen. The rapid growth of the Web in the mid 1990's prompted a sense of urgency in solving this problem and a 1998 sabbatical provided an opportunity to undertake some experiments.

In 1972 I studied the design of learning facilities at Indiana University with Visiting Professor Gerald McVey. I was introduced to Robert Sommers' chapter Small Group Ecology, in his 1969 volume *Personal Space*; it then seemed particularly trenchant. It still is. Sommers showed the seating chosen by library users for different sorts of tasks. Those engaged in cooperative tasks tended to select arrangements that facilitated eye-to-eye contact. They also demonstrated a tendency toward adjacency. In the mid-1990's I renewed my acquaintance with Sommers' work and bent it to my purposes.

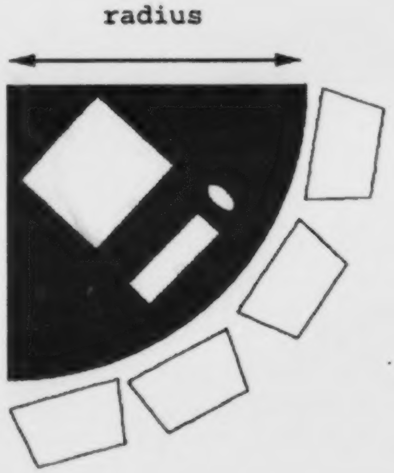
Sommers' insights led me to create a series of cardboard mockups of computer workstations in different shapes and sizes. These were tested with small groups of students. Their feedback in turn resulted in the design and construction of two working prototypes, one shaped something like a horseshoe, the other like a wedge of pie. The stations were provided with large 21 inch monitors and armless chairs with castors, to facilitate easy movement by users. These workstations were placed in a student computing area; faculty were asked to bring or direct their students to these stations, and, with their consent, I observed the student's interactions.

It was quickly apparent that students working at these stations spent greater time on task, that more individuals participated in activities, and that their products were more representative of the group than of some leading individual. This prompted further experimentation on more subtle variations.

The hallmark of all these designs has been the use of a partially circular table, with the learners literally gathered 'outside the circle.' This circular form has become a sort of trademark for our subsequent efforts.



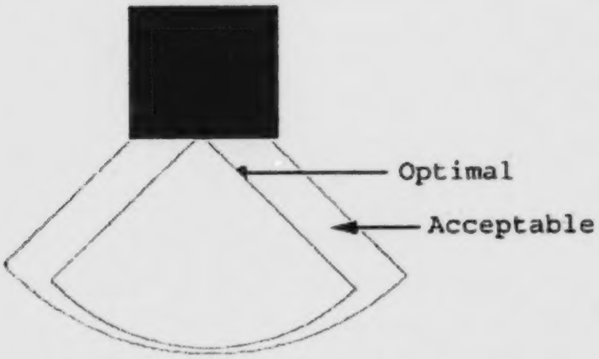
Horseshoe Table



Wedge of Pie Table

The Horseshoe model has proved the most popular design of several we have tried and has become the progenitor of most of our later efforts. The Wedge of Pie model is also effective, but less effective and less popular than the Horseshoe. This apparent difference is probably due to the superior sight lines provided by the Horseshoe model.

These units require satisfactory sight lines AND fields of view, as in the drawing below:



Optimal and acceptable fields of view

In a well-conceived installation, each participant should have good sight lines to the screen and to every other participant, without excessive movement being required. And each participant should sit within at least the acceptable field of view. It is typically the fields of view that determine realistic seating capacity at a particular table.

Our empirical development process led me to postulate some norms for the design and construction of our collaborative stations. The dimensions of the furniture and equipment appear to occupy a narrow range if the stations are to be effective.

The Horseshoe Table needs to occupy a rather narrow range of sizes for effective performance, ranging from 4 to 5 feet in width, and 4 to 5 feet in depth. Width determines seating, or is determined by the desired number of seats. Depth needs to be determined by equipment: larger computers and large CRT monitors require more depth, while smaller computers and LCD monitors can get away with slightly less depth. Here are the combinations we currently favor:

Width	Seating capacity	Monitor (diagonal)	Depth
42 inches	3 (4 very difficult)	19" is adequate	48-54 inches
48	3 or 4	19-21"	48-54 inches
54 inches	4 (5 is difficult)	21-22"	54"
60	4 (5 is manageable)	21-22"	60"

We have found 21-22" monitors to be cost effective in current units, thanks to drops in pricing. We normally configure monitors at SVGA or XGA resolution, as required to insure that everyone can read text adequately. Monitors are set as far back on the tables as is practicable to increase field of view.

Keyboards and mice are simply placed on the tabletops without mouse pads, and passed from one user to another. While we at first anticipated a need for wireless keyboards, the wired version has proved quite adequate. The larger tables also provide adequate room for some ancillary devices such as scanners.

The Wedge of Pie units do function adequately and prove useful in certain locations where corners or rooms are available. The optimal dimensions for these units require a radius from 4 to 5 feet, and, as with the Horseshoe units, larger installations require larger monitors.

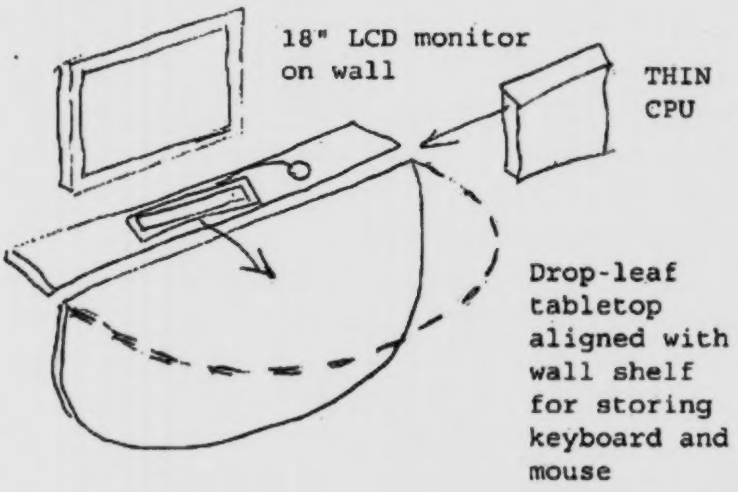
New Options:

The original workstations were used outside of class by students, or by students and faculty. It gradually became clear that some faculty wanted the benefits of such workstations WITHIN their classrooms. This was often expressed as 'responding to class interests,' or 'the teachable moment.'

Our college has responded with energy to the desire of faculty for 'smart' classrooms equipped with a computer and data projector, and for 'studio' classrooms which also have a number of computers for individual students AND a central seminar table. These options do not permit small groups of students to work together, however, and so we have explored other options.

Two new types of facilities have emerged. While similar, they each have distinct features:

1. A language facility, recently funded, provides for a convertible classroom in which the teacher can change configurations in a very brief time by moving chairs and sending learners to stations that are installed along walls. These are described as the 'barnacle' model and the prototype is under construction as of this writing. (It should be in operation by the time this paper is actually presented, and will be illustrated on the website.) This room is intended to provide maximum flexibility for ongoing classes so that a teacher can show a videotape clip, hold a discussion with all students, send groups to computers, and bring everyone back for a meeting of the whole, all within a single period. This room will be assigned to courses for an entire semester.

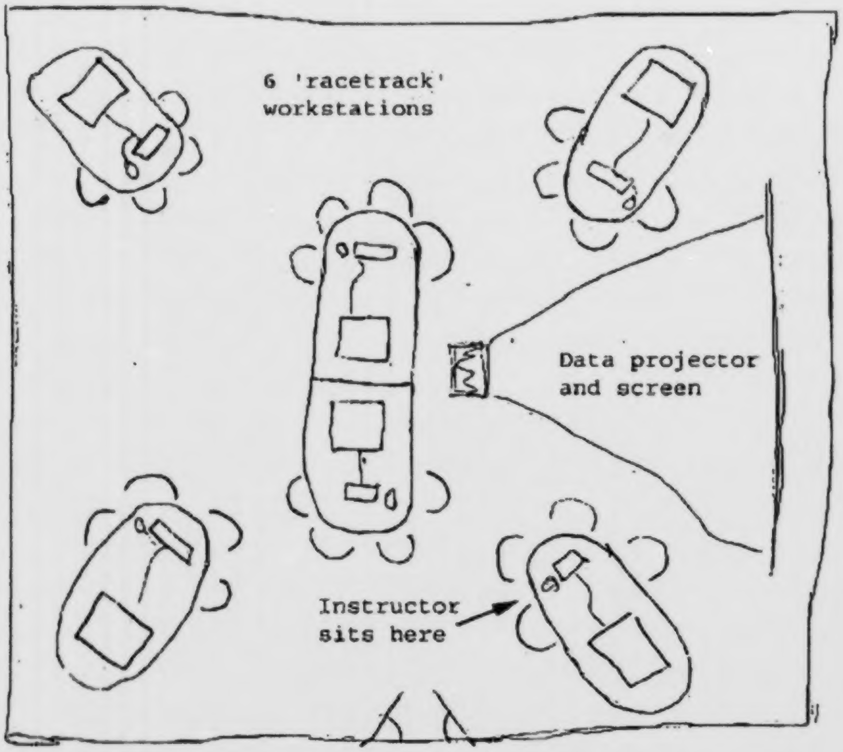


18" LCD monitor on wall
THIN CPU
Drop-leaf tabletop aligned with wall shelf for storing keyboard and mouse

The barnacle unit has been designed to occupy only 9-10" of depth along a classroom wall. We are placing 4 units in the initial classroom, along with an instructor's station designed to do double duty as a group workstation. In a classroom equipped with simple tables and chairs, it will be possible to switch modes very quickly. These installations will take up very little floorspace, so will not have a negative impact on existing classrooms. These stations depend on the availability of affordable 18" or larger LCD monitors and the recent availability of compact CPUs that can be mounted on their sides in tower fashion.

BEST COPY AVAILABLE

2. The second facility is somewhat similar in its equipment but radically different in its expected application. (Its equipment is being installed as of this writing and, again, updated information will appear at the website). This model is designed SOLELY for group activities. Located in the Library as part of our Information Commons project, this room is equipped with six workstations each seating up to four learners. Each station is equipped with a compact computer, a scanner, and a large (22" diagonal) monitor. Station dimensions are detailed below. The room also incorporates a data projector and a player for video/DVD. The room is intended to be available on a period-by-period basis for courses, and will be available for use by groups working outside of class at all other times.



The use of an oval 'racetrack' table may seem unusual; the rounded rear of the tables is a somewhat cosmetic feature that responds to the tendency of janitorial staff to align straight lines in furniture with adjacent walls. As we wanted four of the tables to 'float' at roughly 45 degree angles to the walls, we chose to use a circular form at each end.

Both facilities should be regarded as well-informed experiments.

Collaborative Learning in face-to-face groups ("f2f")

Any group of faculty will offer a range of motivations for wanting to use collaborative learning. Some simply seek a change from more traditional modes of instruction. Others are committed to group processes because they believe it reflects much of the actual work and learning that takes place 'in the real world.' Still others subscribe to constructivist theories of learning and believe that it is only through their own self-aware and active engagement in the learning process that learners can be come autonomous.

While the notion of collaborative learning has held buzzword status for a number of years and is generally thought to be a "good thing," it is important to isolate several types of collaboration that may be taking place simultaneously.

a. Using technology: every collaborative group in these environments spends some time simply using the relevant technology; this usually involves a learning component and a series of decision components. In creating a PowerPoint presentation, to give a simple example, it frequently happens that some students are more adept with the software than the others. They share a number of simple decisions about what features to use, and some learn technology skills from others. In this instance we often suggest that faculty tell students to 'pass the mouse' to insure that all participants literally have a hand in the mechanical process. This can run contrary to student wishes, as the learners would often prefer to leave the manipulation of the technology to those who are already adept.

   Sometimes the use of the technology is actually the primary learning goal for part of a lesson. Students learning to manipulate library catalogs, for example, may be encountering software that is new to every member of their group, and a strategy for insuring that each group member participates is essential. This is a situation in which the presence of the instructor during the learning session is very important.

b. Much of the time collaboration will entail manipulating higher level, less mechanical concepts. The design rather than the construction of a PowerPoint presentation, or the search for information upon which to base it, is one example. Making decisions about video edits is another. Here, the role of the instructor is more similar to that in traditional class discussions: helping learners to weigh ideas, to consider other options, encouraging the group to find a consensus that exceeds some least-common denominator.

c. Students also engage in a range of social collaborations. Some of these are inevitable and desirable, while digressive behavior needs to be contained. Faculty may do best by encouraging students to focus on assigned tasks rather than remonstrating about digressive behavior. It is important for both students and faculty to recognize that purely social activity is not the same thing as collaborating. However, it is equally important for faculty to recognize that effective collaboration virtually requires a social dimension, and that practice in social negotiation is an important aspect of the process for undergraduates.

These forms of collaboration and perhaps others are all interwoven in practical learning situations. At one moment the group is being social, an another it considers technology, and at still another it works on a higher level goal. The group will alternate rapidly among these modes.

It is also very important to recognize that learners come to the collaborative process with a range of skills and a range of motivations, that they are by no means equals. The recent literature has made it clear that there are differences among learner's success rates in face-to-face and online collaboration. Since some individuals are more confident in working online than in live groups, it makes sense to create both face-to-face and online aspects for group learning tasks. It may well make sense to begin collaborative tasks on line in order to help enfranchise the more reticent members of the group, then use that experience to help cement the face-to-face groups.

My office supports students and faculty using group workstations. Over time, it has become quite evident that some faculty profit from some assistance in structuring assignments, and some students need some feedback or prompting during the learning process. These two needs are in some ways more interesting than the facilities themselves.

Consider this example: A faculty member new to PowerPoint decided that program offered beneficial possibilities in the learning process. The student groups were to manipulate this presentation medium and create presentations that they obtained from external research. The instruction was to 'create a PowerPoint presentation, ' which seemed analogous to the instruction 'write a paper.' The creation of papers, however, is undergirded by years of experience on the parts of both teacher and learners. Few teachers or students have anything approaching that depth of historic experience with PowerPoint. Somewhat predictably the groups created presentations with excessive reliance on transitions and effects that contributed little to the communications and actually reduced quality. The instructor was disappointed by this result, but thought the collaborations had worked well. Conducting a *post mortem*, we discovered that the instructor had felt apprehensive about personal PowerPoint skills so had stayed out of discussions, simply watched the groups from afar. More active feedback to the groups would have prompted more time on the higher level issues, and less on technical frills. In fact, a second round of sessions with the same instructor was found to be much more satisfying.

As antidote to these sorts of problems, I offer faculty a (growing) series of heuristics that can help guide them in using electronic tools for collaboration.

Conclusions:

The results of our most recent experiments will be on hand by the date of this presentation. We have high expectations for both the 'barnacle' and the collaborative classroom models. We will be tracking performance of both in-class and out-of-class users. Our past experience with collaborative facilities has been very positive, and these new facilities should run true to form.

A Case and Implications of Implementing and Evaluating an Online Virtual Learning Community Environment

ABSTRACT

The knowledge distributed web-based learning community (KnowDisLC) based on knowledge sharing for college students has been constructed, implemented and evaluated. The system helps students form a virtual learning community through web-based learning, which they can use to facilitate learning and growth. Ultimately they would like to accomplish the goals of knowledge sharing, resource sharing, information exchange, experience interchange, and emotion communication. Both a point accumulation mechanism and a web-based learning record have been the features of the KnowDisLC system, which prove to stimulate student involvement by allowing them to know about the performance and involvement of themselves and their peers. Most students agree that the community could help them learn more and faster, and most students also confirm that the overall operation and implementation of the system is generally good.

LEARNING COMMUNITY ON THE WEB

Although some research in Taiwan on web-based learning environments and knowledge guidance systems for in-service teachers has noted the concepts of a learning community, none of them has developed any system based on the complete idea of a learning community. However, there are many related systems, documents and research all over the world. Founded on the concept of community of practice, CoVis (Learning through Collaborative Visualization) aims at research related to science learning (climatology and geology) (Pea, 1993). It provides online discussion, e-mail, teleconferencing and other WWW tools to link experts, teachers, students and field workers to form a collaborative learning community. Students may actively learn through participating in knowledge building, knowledge sharing and collaborative-based activities as a member of an online group (Brandon & Hollingshead, 1999).

CSILE (Computer-Supported Intentional Learning Environment) is a kind of collaborative database style of learning community which aims at providing students with strategic tools that can stimulate thinking. In CSILE's collaborative database, students can share knowledge asynchronously. A student can access the thoughts of the present or former students and can leave his own thought for other students. CSILE was used in the context of a community with emphasis on "knowledge building and sharing" instead of "knowledge inoculating." An evaluation by Scardamalia & Bereiter (1994) of the CSILE project clamed that the collaborative learning community formed by students facilitated knowledge building and generated positive learning outcomes with the use of telecommunication technologies. Whereas use of technology does not absolutely make a community occur, a learning community needs to be planned and created.

SYSTEM ENVIRONMENT

The KnowDisLC provides access to utilities that include an ID verification center, news bulletin board, counter of online user number, discussion board, curriculum center, learning activity bulletin, learning resources browsing and sharing, user profile center, expert consultation, website resource searching, opinion bulletin board, point accumulation system, web-based learning record, and system management. Dynamic HTML flexible menu has been adopted in the system to avoid a problem of long screen resulting from too many sub-menus of functional buttons.

The construction of a point accumulation system for learning activity is one of the features of the KnowDisLC system. It displays both the learning score and frequency of visits of each user. It is a reference for performance evaluation of students. To increase student motivation, the system gives users different scores according to their involvement in the web-based learning, e.g. logging on to the system (1 point a day), sharing and provision of file resources, sharing and provision of related websites, participation in discussion (raising questions and making replies), moderating a discussion or conference. The second feature of the KnowDisLC system is its web learning status log, including learning log statistics, conference records, assignment upload statistics, performance statistics for discussion or conference moderators, etc. This facility can be used by students in order to find their learning status at anytime and use it as a reference for correction. The website and file resource browsing and sharing functions are based on the concepts of sharing and provision of knowledge, distributed knowledge, knowledge building, and information exchanging. This is the third feature of the KnowDisLC system. Community members can enter or link to the URL address of a related learning resource site and upload/share or download/browse files of materials related to course subject for the goals of collaborative academic growth.

IMPLEMENTATION AND ISSUES

The aim of the implementation of the KnowDisLC was to observe the collaborative learning that was taking place in the system. Since the development of the KnowDisLC, we have been using it as part of teaching materials in the class and self-oriented learning materials after the class of "Distance Education" in my Department. Students study the "Distance Education" course through learner-centered, inquiry-based, discussion-oriented, and project-based learning activities in the virtual social community on the Web environments.

It began in 2001 Spring Semester with 67 college students in our department as well as 1 teacher, 1 online assistant and 1 field expert. It has now expanded to include around 103 college students as well as 2 teachers, 2 online assistants and 2 field experts in "Distance Education" course. The KnowDisLC is committed to supporting the spread of project-based learning in which students formulate their own questions, exchange their information, provide distributed knowledge, share learning resources, collaboratively work on their project and homework, build their own knowledge, while being guided and facilitated by their teachers, field experts, and experienced students (Cang, 2000).

The course required students to evaluate other students' posts and replies in discussion, information sharing and resource provision. The teacher required students to collaboratively find a case study using real-world problems or cases and to collaboratively analyze information and propose a resolving method as part of their response.

We used project-based collaborative learning to develop transferable skills, enhance knowledge-building, facilitate teamwork and mentor skills of the students. Students were encouraged to do collaborative exercises by sharing ideas, exchanging information, providing resources, and constructing knowledge toward finding a solution to their common learning objectives. Students shared the idea and knowledge by uploading learning materials, providing the addresses of web sites, and posting the idea in the discussion board. During group collaborative learning and doing project, groups of 3-4 students solve a problem or create a teamwork product collaboratively through the use of a conference room, discussion board, e-mail, and mailing listserv. Groups of 3-4 students were assigned problem-based learning exercises in the courses to solve collaboratively.

Implementation results of the KnowDisLC showed that using the telecommunication technologies took more time than learning the on-line course materials and participating in the learning activities on the web. Based on a review of the records of web activities, the more actively the students participated in the web-based activities the better performance students had in classroom instruction. In other words, highly motivated students generally participated much more than poorly motivated students. It reveals that there is a positive correlation between the participation in web-based learning activities and the participation in classroom instructional activities.

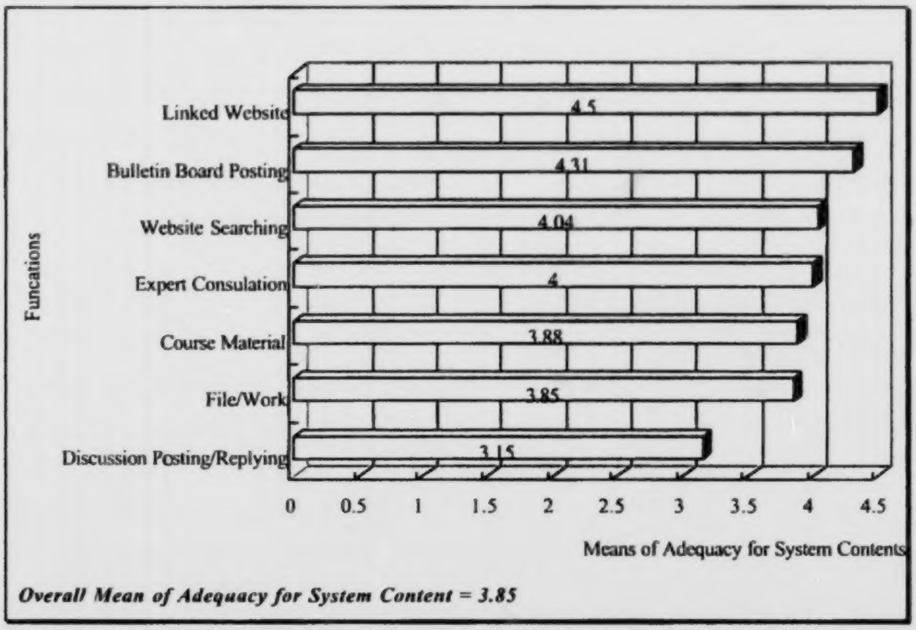
This results are quite consistent with a study of the Virtual Classroom by Hiltz' (1993) concluding that students with a high level of academic performance and self-motivation in classroom setting would have more positive outcomes on online activities. Using the telecommunication tools on the virtual learning environment, college students have access to large amount of information and knowledge provided by their peers in the class and experts in the field.

SYSTEM EVALUATION

An evaluation of the system was conducted right after the 3-month implementation of the KnowDisLC. Its purpose was to understand the effects and pertinence of the implementation of the KnowDisLC in university education. A target group of the evaluation consisted of 67 students who took the courses. They were all required to use KnowDisLC and gave comments related the system. The evaluation was conducted through a questionnaire survey; a self-developed 5-point Likert rating scale evaluation form was distributed to the students. After the evaluation, students completed the questionnaire. The questionnaire included six main evaluation items : system contents, screen design, user interface, system functions, use frequency, and learning effects. Resulting from the survey of students' satisfaction showed that in general, they rated their learning experiences in the web-based learning environment consistently higher than those in the instruction of traditional classrooms. As far as the students' feedback on the satisfactions for the content, interface, and functions of KnowDisLC system reported that the system interface was easily accessible and usable to users.

System Content

In the comparison of the content adequacies of KnowDisLC elements, students perceive that *linked website* is the most adequate element for content (mean = 4.5). As high as 92.3% of the students regard *linked website* adequate to support their learning. Only 7.7% of the students think otherwise. The subsequent elements are *bulletin board posting* (mean = 4.31), *website searching* (mean = 4.08) respectively. Adversely, students perceive that the *discussion posting and replying* (mean = 3.15) is the least adequate elements for content. 34.6% of the students regard that quality and quantity of the *discussion posting and replying* are adequate to support their learning. 23% of the students think otherwise. These results reveal that students' posting and replying in discussion board need to be improved. As a matter of fact, we also regard that there are actually much room for improvements such as course materials, and file/work. Figure 1 shows the distribution of the means for student comments on the content adequacies of KnowDisLC elements.



Overall Mean of Adequacy for System Content = 3.85

Figure 1. *The distribution of the means for student comments on the content adequacies of KnowDisLC elements*

User Interface

In the comparison of the interface applicability of KnowDisLC elements, students perceive that the interface of *opinion bulletin board* is the most used-friendly (mean = 4.46). As high as 92.3% of the students regard the interface of *opinion bulletin board* easy and convenient to operate. No one (0%) thinks otherwise. The subsequent elements are *online registration* (mean = 4.38), *ID verification center* (mean = 4.35), and *website sharing* (mean = 4.27) respectively. Adversely, students perceive that the interfaces of *synchronous conference room* (mean = 3.58), *online calling* (mean = 3.69), and *course material* (mean = 3.81) are the less used-friendly. As high as 61.7% of the students regard that the interface of *synchronous conference room* easy and convenient to operate, however, 26.9% of the students think otherwise. Figure 2 shows the distribution of the means for student comments on the interface applicability of KnowDisLC elements.

BEST COPY AVAILABLE

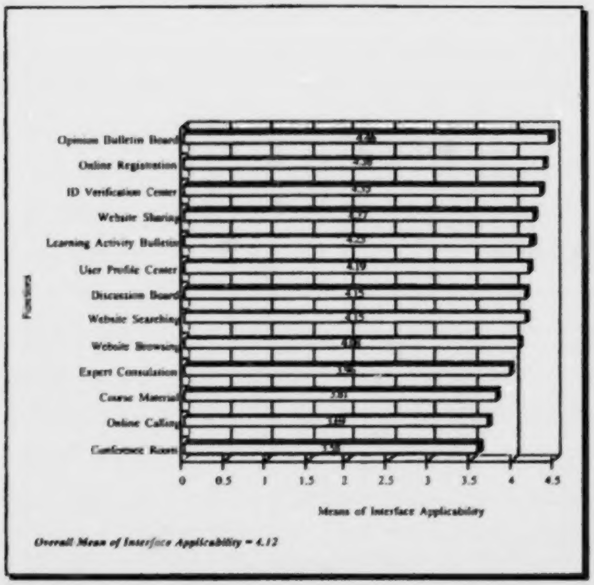


Figure 2. *The distribution of the means for student comments on the interface applicability of KnowDisLC elements*

System Functions

In the comparison of the functional applicability of KnowDisLC elements, students perceive that *ID verification center* is the most applicable-functionally element (mean = 4.31). As high as 80.8% of the students regard function of *ID verification center* applicable to use. No one (0%) thinks otherwise. The subsequent elements are *activity bulletin board* (mean = 4.19), *news bulletin board* and *asynchronous discussion board* (mean = 4.15) respectively. Adversely, students perceive that the *website index* (mean = 3.5), *file/work resource index* (mean = 3.54), and *synchronous conference room* (mean = 3.54) are the less applicable-functionally elements of the system. 53.8% of the students regard that the *website index* is applicable to use, however, as high as 26.9% of the students think otherwise. Figure 3 shows the distribution of the means for student comments on the functional applicability of KnowDisLC elements.

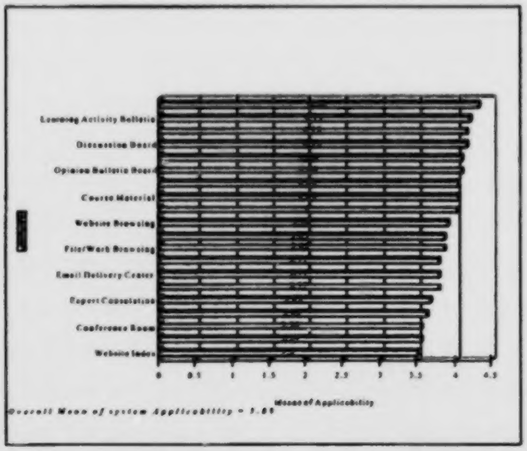

Figure 3. *The distribution of the means for student comments on the functional applicability of KnowDisLC element*

BEST COPY AVAILABLE

Use Frequency

Most students approve of the overall operation and instructional application of the KnowDisLC system, whereas, there are still some functional elements that are rarely used by students. The less-frequently used functions include *expert consultation, website sharing, online calling, ………, synchronous conference room* and so forth. The results show that although the system functions and learning effect are generally both good, there is still wide room for improvement with uses, operation, implementation and management of the system.

This low use of the system in comparing with the system contents, screen design, user interface, system functions, and learning effects, the performance of the users in terms of system use seems to be far behind. This phenomenon shows that even if the system is a rather good one, the users may still encounter other practical difficulties in using it. These difficulties might be the key factors that decrease the successful possibility of online learning community. Therefore, it has turned out to become an issue worthy of further research and investigation.

In the comparison of the use frequencies of KnowDisLC elements, students perceive that *news bulletin board* is the most frequently used element (mean = 4.19). As high as 76.9% of the students frequently visit *news bulletin board* to see news announced by the teacher or system manager. No one (0%) rarely visit *news bulletin board*. The subsequent elements are *asynchronous discussion board* (mean = 3.42), and *website searching* (mean = 3.42) respectively. Adversely, students perceive that the *expert consultation* (mean = 2.0), *website sharing* (mean = 2.58), *and online calling* (mean = 2.77) are the most rarely used elements of the system. No one frequently ask question for the expert (0%). As high as 65.4% of the students rarely ask question for expert. In comparison with overall mean of the system use (overall mean = 3.25), the means of use frequencies for these three least used elements seem to be quite behind. Figure 4 shows the distribution of the means for student comments on the use frequencies of KnowDisLC elements.

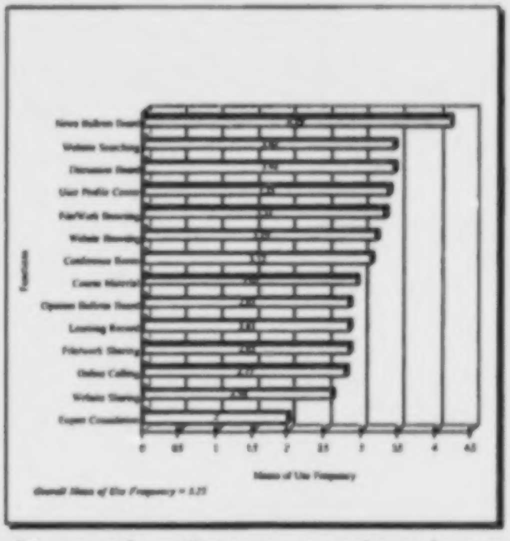

Figure 4. *The distribution of the means for student comments on the use frequencies of KnowDisLC elements*

Impacts on Learning

In terms of negative comments on the effects of KnowDisLC, 11.5% of students regard that the articles in the *asynchronous discussion board* posted are not beneficial to their academic growth (mean = 3.65). As high as 23.1% of the students regard that the communication mode in the *asynchronous discussion board* cannot enhance the interaction between them and other students (mean = 3.46). 15.4% of the students regard that the discussion mode in the *online synchronous conference room* cannot promote their abilities of discussion with people (mean = 3.5). 11.5% of students regard that the *opinion bulletin board* cannot make them know the feelings of other students and cannot achieve the goal of emotion communication (mean = 3.58). However, averaging the above two items (mean = 3.65+3.46 = 3.56), the mean of usefulness for the *asynchronous discussion board* will be 3.56; thus the perceived least beneficial element of the KnowDisLC system will be the *online synchronous conference room* (mean = 3.5).

BEST COPY AVAILABLE

In the comparison of the effects of KnowDisLC elements, students perceive that *point accumulation system* is the most beneficial element (mean = 4.23). As high as 80.8% of the students regard *point accumulation system* useful to stimulate learning motivation and make their learning outcomes better (mean = 4.23). Only as low as 3.8% of the students think otherwise. The subsequent elements are *resources browsing* (mean = 4.08), *course material* (mean = 4.08), *file/work* (mean = 4.08), and *linked website* (mean = 4.0) respectively. Adversely, students perceive that the *online synchronous conference room* (mean = 3.5), *asynchronous discussion board* (mean = 3.56), and *opinion bulletin board* (mean = 3.58) are the less beneficial elements of the system. *online synchronous conference room* is the least effective element (mean = 3.5). However, in terms of interactive effect, it is slightly more interactive than *asynchronous discussion board*. As high as 15.4% of the students regard that the discussion mode in the *online synchronous conference room* cannot promote their abilities of discussion with people (mean = 3.5). In comparison with overall mean of the system (overall mean = 3.89), the means of effects for these three least effective elements seem to be quite behind. Figure 5 shows the distribution of the means for student comments on the effects of KnowDisLC elements.

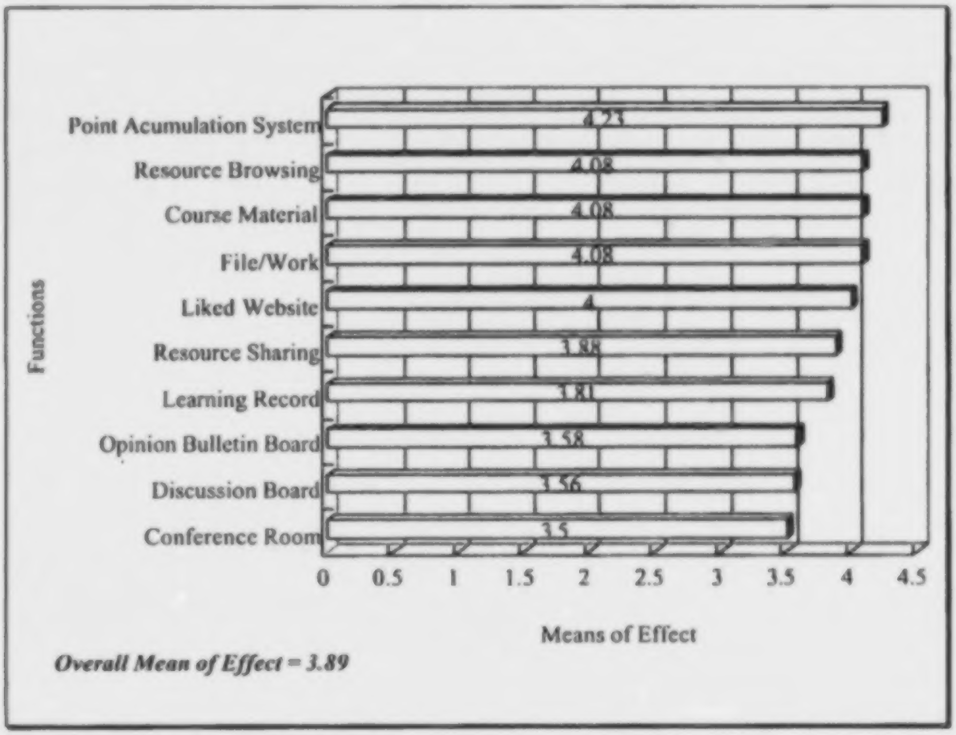

Figure 5. *The distribution of the means for student comments on the effects of KnowDisLC elements*
Note: Resource includes file/work resource and website resource

IMPLICATIONS AND LESSONS LEARNED

There were many lessons learned regarding the KnowDisLC system, from physical setup to technological support, to teachers' teaching preparation, and to students' learning experiences and so forth. Important considerations about technological support were: the reliability of the server and the system software, the technical support available for the users, less waiting time when browsing and navigating system, friendly use of the system interface, and easy access to the system content, and so forth.

Over the past semester, the successes of the KnowDisLC have argued strongly for the value of web-enhanced learning environment for college students. The creation and implementation of the KnowDisLC system has obtained

BEST COPY AVAILABLE

high support from students and teachers, therefore additional materials for other courses provided by the Department are being developed. Integrating traditional classroom instruction and web-based learning appears to have become a major departmental focus primarily due to the greatly successful experiences of the creation and use of the KnowDisLC system.

Based upon the observation of the learning behaviors taking place at the KnowDisLC, it is apparent that the facilitators such as teacher, tutor, and online teaching assistant have an important role to strike the desired balance of motivator, mentor and mediator which can affect the success of a learning community. The role of teacher is changed from a knowledge provider to an informational facilitator and a learning mentor. Teacher has become guides and coaches, while students have taken a more active role during the learning process in the KnowDisLC. Students in the learning community gain more attention from instructor and online assistant. Additionally, they may spend more time thinking about, responding to, and exploring, whatever question peers or instructors give.

One interesting observation is that the grade point computing system resulted from the records of web activities such as login frequency, staying time on web, discussing frequency (post and reply), the frequency of learning resources provision etc. may highly stimulate more students to actively participate web-based learning activities. Additional, allowing students to view each other's work and project appeared to result in a better expression of ideas among them.

The web-based learning environment may play a great role of equalizer through providing an alternative for students to participate in the web's interactive activities such as asking questions and discussions, and to actively give feedback to each other and to instructor. Just like Palloff and Pratt (1996) claim, introverted students who may not feel comfortable speaking out or asking for help in a face-to-face classroom may flourish in an online learning community. Moreover, most of students gain the gratification of control over their time during online learning and the opportunity to be more thoughtful about their interactions (Palloff and Pratt, 1996, p.164). This kind of equal opportunity is especially suitable to those who shy away from speaking up when face-to-face in traditional teaching situation but who eagerly share their ideas on the web.

Web-based learning absolutely has the positive effects on student participation and learning outcomes. Moreover, it can encourage peer-to-peer interaction, increase student motivation and engagement in the learning process, and reduce some barriers of participation that are present in face-to-face mode. This study identified that a web-based learning environment appears to promote comprehensive and critical thinking as well as to empower and engage active learning. The KnowDisLC has reshaped individual and active learning experiences for many students at our university. Encouraged by the success of the KnowDisLC, we are intended to engage in developing the other learning subjects.

CONCLUSIONS AND FUTURE WORKS

The research has designed, constructed and evaluated a distributed knowledge learning community as an aide to web-based learning, in hopes that it will help students form a virtual learning community through web-based learning. They can use the system to facilitate learning and academic growth through the curriculum center, discussions, conferencing, learning resources browsing and sharing, expert consultation, web resource searching, and opinion bulletin board. Ultimately they would like to accomplish the goals of knowledge sharing and provision, resource sharing and provision, information exchange, experience interchange, and emotion communication. The KnowDisLC provides college students with effective telecommunication and collaboration tools, and students' responses toward KnowDisLC have been very positive and encouraging. The KnowDisLC thus facilitates academic growth and interpersonal interaction of college students through collaborative learning environments and telecommunication tools in the context of a virtual community.

Both a point accumulation mechanism and a web-based learning record have been the features of the KnowDisLC system, which prove to stimulate student involvement by allowing them to know about the performance and involvement of themselves and their peers. The system has been officially implemented in a university course for 3 months, and both the implementation and operation are running smoothly. The system evaluation shows that most users are satisfied with the system contents, screen design, user interface, and system functions. Most students agree that the community could help them learn more and accelerate their professional growth. In addition, they also confirm that the overall operation and implementation of the system is generally good.

With regards to use frequency of the KnowDisLC system, most students approve of its overall operation and instructional application. However, there are still some functional elements that are rarely used by students. What we have received negative feedback are the less-frequently used functions such as *expert consultation, website sharing*, and *online calling*. The results show that although the system functions and learning effects are generally both good, there is still much room for improvement with using and management of the system functions.

Standard computer-mediated communication technologies of the Internet and the Web are used and benefit has been obtained from the development in the KnowDisLC system. The establishment of a virtual distributed and collaborative learning community will be an important outcome dedicated to college teaching and learning. KnowDisLC certainly has its problems and limitations, but the lesson of its developing and implementing experience in creating a lively social system is that there are knowledge-sharing mechanisms that can have an important effect on encouraging active learning and thus successful online learning communities.

In the future, we will reinforce: expansion and maintenance of system functions; the automatic management, and learning management in particular(such as a mechanism of learning resources establishment and management); web page browsing record and learning path management; web-based learning duration and log-out time; learning resources and website browsing time; automatic approval functions of website upload; graphic display and full text indexing of discussions board and activity bulletin; cross-disciplinary uses of the system; an online assessment (e.g. web-based portfolio), in order to optimize the system. Subsequent research will also include qualitative and quantitative experimental studies of the system, in order to understand more about students' learning behavior pattern and its authentic effects on the students.

Assessing the Usability of MOA Interface Designs

Yaowen Chang
Teachers College
Columbia University
yc371@columbia.edu

Abstract: This study evaluates the usability of the proposed MOA (mouse-over-abstract) interfaces that could be implemented in web-based or stand-alone applications. The MOA designs provide users with an abstract that serves as context cues about the information presented in the linked page. The context cues are available in visual and/or audio formats. Evaluation of the MOA usability focuses on its affordances in efficiency, effectiveness, and user satisfaction. The proposed study aims to examine the influence of the MOA interfaces and presentation modality on program usability. The study also aims to evaluate the relationships among the three aspects of usability. Findings of the proposed study have implications in bridging the gap between research and practice. While results serve as empirically tested guidelines for interface designs applicable for computer-based learning programs, the application of study results also set examples for usable educational research.

Rationale

In the digital era, an information space contains more than text. The incorporation of the Internet and interactive multimedia have provided users with alternative ways of handling information. Hypertext structure, for example, allows the user to share the authorship of the intended reading. Consequently, there has been an ample amount of research conducted on user behavior in the electronic information space, and best practices have been suggested regarding information use within the digital medium. Studies that have contrasted reading on screen from reading printed matter (Dillon, 1992; Egan, Remde, Landauer, Lochbaum, & Gomez, 1989; Martin & Platt, 2001; Poynter Institute, 2000) support the notion that the electronic information space is more than just a variation of document media. Users actually develop ways to interact with the electronic information space that are substantially different from how they would interact with other media.

Traditional information space – such as books and journals – provides facilities such as tables of content, headings, and abstracts. This "meta-structure" serves to make both the organization and content of the material explicit to the user. Given that such improvements in the design usability of printed material has been an evolutionary process that has lasted at least 500 years (Febvre & Martin, 1976), it is reasonable to expect that it will also take some time before we come up with the best meta-structure for information retrieval in the electronic space. As a result, the usability of the electronic information space is an issue worth addressing.

Conceptual Framework

Usability

Although "usability" is a term that has been widely discussed, there is a lack of consensus on its definition (Jordan, 1998; Marchionini & Crane, 1994). Numerous authors have adopted the definition of the ISO (1998), by which effectiveness, efficiency, and user satisfaction are the three aspects of usability.

Evaluation of the general concept of usability is then made possible by concretely defining the parameters of the three terms (Frøkjær, Hertzum & Hornbæk, 2001; Nielsen & Levy, 1994).

Effectiveness is usually measured by the extent to which an intended task is successfully completed. *Efficiency* refers to the amount of effort it takes to complete the task and may be measured according to indicators that include deviations from the correct path, error rate, the amount of time spent, and mental workload. *User satisfaction*, the last component of this product usability scheme, refers to how comfortable users are using a certain product to achieve a specific goal; user satisfaction is usually measured using the method of self-report. While effectiveness and efficiency yield measures of objective performance, user satisfaction provides insight about subjective preferences of application users.

It has been suggested that claims of usability should take into consideration all three aspects of usability as well as their interrelationships (Frøkjær, Hertzum & Hornbæk, 2000; Nielsen & Levy, 1994). For instance, because it is difficult to measure effectiveness as a component of usability, many studies have rested on the assumption that effectiveness equals efficiency of user performance. However, caution should be applied to conclusions based on such assumptions, because it remains to be proven that effectiveness is reducible to efficiency. In essence, when examining product usability, one must recognize the interplay among the defining properties.

Web usability and information seeking

The evaluation of Web usability can not be conducted without the context of information-seeking behavior. This is because the evaluation criteria of Web usability -- such as effectiveness, efficiency, and user satisfaction – are essentially the perceived outcome of information-seeking activities. According to Marchionini (1995), how someone interacts with the information space is determined by the given individual's "personal information infrastructure." This personal information infrastructure is a constellation of interconnected mental models.

The concept of mental models (Johnson-Laird, 1983) is one of the theories proposed by cognitive psychologists to explain human cognitive activities. The mental model theory proposes that individuals react to situations or make predictions about circumstances in reference to their pre-existing mental models. In other words, the mental models serve as the individuals' inner template of the real world. In the present case, a mental model about the content of a Web page will allow the reader to make predictions about the material; thus, it may facilitate – or impede – the reader's comprehension of the information being presented.

Previous research findings support the notion that mental models play an essential role in information-seeking behavior (e.g., Borgman, 1986; Dimitroff, 1992; Liebscher & Marchionini, 1988; Kerr, 1990; Webb & Kramer, 1990). In fact, information seeking may be viewed as the process humans undertake specifically in order to modify their mental models – by changing the state of their knowledge so as to better resolve internal contradictions. It is assumed that, when an information problem is detected, information-seeking behavior is initiated in order to repair the perceived deficiency.

Web-usability problems

Although there has been much discussion about Web-usability problems over the years, there is still a lack of consensus on what the core difficulty is (Marchionini, 1995; Toms, 2000). It has been suggested that some problems might be due to the fact that certain information used to navigate printed text is not available in electronic text environments. Two of the oft-cited Web-usability problems are *cognitive overload* and *disorientation*.

The term cognitive overload or information overload is usually used to describe a state wherein the received information becomes a hindrance rather than a help. Even though cognitive overload is not a new concept, it was not until the 1990s that this phenomenon started to be perceived as a major problem associated with the new technological advances (Bawden, Holtham & Courtney, 1999).

Disorientation – or "getting lost in cyberspace" – is another negative consequence of information seeking in the electronic information space. Conklin (1987) defined disorientation as the users' tendency "to lose their direction and sense of location" in a non-linear information environment. It has been suggested that such phenomena might be due to factors such as unfamiliarity with the document structure (Foss, 1989) and lack of contextual cues (Park & Kim, 2000; Soderston, 1986).

Over the years, various types of interface designs have been proposed to tackle Web usability problems (e.g., Florance, 1992; Foss, 1989; Furnas, 1986; Gecsei & Martin, 1989; Hammond & Allinson, 1987; Kerr, 1989; Park & Kim, 2000). Most of these meta-structural designs aim to help users have a sense of what kind of information is to be found, where they are in the system, and how to move around the information space without incurring cognitive overload (Toms, 2000). Essentially, a lot of these designs aim to deal with issues such as cognitive overload and disorientation by providing users with *context information*.

Context information is here defined as the explanation of the user's current situation in the Web environment. For instance, Park and Kim (2000) conducted a study to examine the effectiveness of contextual navigation aids in Web browsing activities. It was found that participants preferred the Web system with context information. Provision of context information also seemed to increase the efficiency of users' information-seeking activities. Over the years, various types of interfaces have been proposed to facilitate users' information-seeking behavior in the electronic information space (e.g., Conklin & Begeman, 1989; Egan, Remde, Landauer, Lochbaum & Gomez, 1989; Florance, 1992; Foss, 1989; Furnas, 1986; Gecsei & Martin, 1989; Hammond & Allinson, 1987; Nielsen, 1990; Webb & Kramer, 1990). Most of these designs present information through visual rather than audio channels.

In response, the current study aims to propose an interface design called MOA, an acronym for Mouse-Over-Abstract, that provides Web users with context cues in visual *and/or* audio formats. The context cues appear when users place the mouse over a hyperlink and they are abstracts of the information presented on the linked page. It is anticipated that such contextual cues will serve as landmarks in the hypertext environment to ameliorate the issue of disorientation and, therefore, minimize the amount of cognitive load attributable to navigation.

Following are some questions concerning the evaluation of the proposed design.

1. Do participants perform better with, and show a preference for, MOA interfaces as opposed to an interface that does not have this feature?
2. Do different modalities (e.g., text, audio) of MOA interfaces result in differential degrees of participant performance and/or preference?
3. What are the relationships among the three aspects of usability: effectiveness, efficiency, and satisfaction?

Methodology

Participants

Eighty participants will be recruited from colleges and universities in the New York metropolitan area. There will be a twenty-dollar compensation for their one-and-a-half-hour participation. Educational level and experience with computers and computer-mediated information systems have been found to be confounding variables of usability. As a result, eligible participants will need to have at least a college-level education and have at least three years of experience with computer-based information systems.

Materials

The domain contents in the current study will include both natural science and social science topics. Content materials will be provided and edited by experts in the given fields. Content experts were given three guidelines to take into account when choosing their topics. First, the difficulty level of the domain content should be comprehensible for individuals with a college-level education. Second, contents should not be easily guessable, and comprehension of the given content should require the user's efforts and cognitive processing. Third, the topic should be interesting to the general public. Based on these guidelines, two topics were chosen.

The natural science topic addresses the specific question: "Why does the moon have phases?" The social science topic concerns the functions and histories of Institutional Review Board.

Two Web applications will be generated based on the provided contents. Subject materials will be divided into subsections and presented in HTML format. JavaScript will be used to develop the interface needed to present the visual and audio context cues. Basic interface design of the Web pages will adhere to general guidelines suggested by Web usability experts (e.g., Nielsen, 2000).

Experimental treatments

The current study involves four kinds of interfaces including one control interface and three experimental interfaces. Participants in the experimental groups will be presented with the MOA interfaces that provide context cues when they put the mouse on a hyperlink. One MOA interface provides context information in text format, another in audio, and the other contains information in both modalities. No such add-on mechanism is available in the interface for the control group.

Measures

Demographic information. Participants will be required to provide background information on a demographic sheet. These questions include gender, age, level of education, college major, number of computer-usage hours per week, years of experience with computers, years of experience with the Internet, and the computer platform (e.g., PC, Mac) with which they are most familiar.

Efficiency. A system log will be used to record the time participants spend and the links they click on the Websites. Participants will also complete a set of questions, which rates their subjective perception about the mental load during their interaction with the interfaces. The mental load ratings are based on a 7 point Likert scale, with 1 indicating very easy and 7 indicating very difficult. Previous research has indicated the subjective measure easy to administer and as reliable as objective methods (e.g., Mayer & Chandler, 2001).

Effectiveness. After the interaction with the experimental system, the users will be given a set of multiple-choice questions to assess their recollection and comprehension of the domain contents.

User satisfaction. User satisfaction will be evaluated using an abbreviated version of the Shneiderman's Questionnaire for User Interaction Satisfaction. There will be a set of eight Likert scale items included in the questionnaire (Toms, 2000).

Procedure

The experiment will be conducted in the computer lab of the Academic Computing Services located at Teachers College and supervised by two experiment administrators. Equipment required to run the study includes twenty PC laptops with external mouse attached. The applications will be loaded on the hard drives of these laptops before the experiments. Four group experiments are expected be conducted with twenty subjects within each section. Individual sections may also be considered.

At the beginning of the experiment, the participants will be requested to fill out a demographic sheet. After the completed demographic sheets are collected, the participants will be informed that the entire experiment will be divided into two forty-minute sessions with a five-minute break between sessions. Participants will be requested to browse through the provided Websites.

Participants will be randomly assigned to one of the four groups: a) the control group will be presented with the control interface which contains no add-on features; b) the visual group will be provided with the text-based MOA interface; c) the audio group will receive an audio-supplemented MOA interface; and d) the hybrid group will have a MOA interface providing context cues in both visual and audio format. Within each of the four sub-groups, half of the participants will be given the natural science topic first and half the social science topic. Efforts will be made to ensure equal gender distribution among different treatment groups.

After the browsing session, participants will be asked to respond to the measures mentioned above in order to assess the efficiency, effectiveness and user satisfaction properties of the interfaces. Five minutes will be allocated for the mental load ratings, ten minutes for the recollection and comprehension task, and five minutes for user satisfaction questions. At the end of the first session, the participants will be provided with a five-minute break. The break aims to alleviate the possible impact of fatigue on user performance. Upon their return, the same procedure will take place again. In the second session, participants who were provided with the natural science topic in the first session will be given the social science topic, and vice versa.

Anticipated Results

Methods of analysis

Efficiency. Three measures will be implemented to determine the concept of efficiency. First, efficiency (E1) will be measured based on the ratio of the time a participant devoted to reading (Tr), to the total amount of time spent (Tt): E1= Tr / Tt. Second, efficiency (E2) will also be measured based on the number of links required for a perfect path (Cp), over the number of links the user clicked through to complete the task (Cn): E2 = Cp / Cn. For both E1 and E2, a higher degree of efficiency is indicated as a value of E1 or E2 approximating 1, a low degree of efficiency by values approaching 0. These two measures both rest on the assumption that excessive clicking behavior may be a sign of *disorientation*. The total value of the individual mental rating items will be tabulated and serve as a third measure for efficiency. Because an efficient interface should require participants less cognitive load, higher mental load scores represents lower degree of efficiency and vice versa.

Effectiveness. The degree of comprehension (Effectiveness) will be assessed based on the number of correct items (Ic), over the total number of items (It): Effectiveness = Ic / It. A higher degree of effectiveness is indicated as a value of Rec approximating 1, a lower by values approaching 0.

User satisfaction. Summing up users' responses to the eight-item Likert scale questionnaire will generate a total score for user satisfaction. The final score will be used as the final indicator of user satisfaction.

Results

The two-by-two factorial design of the current study results in four groups of twenty participants each, as indicated in the matrix shown in Table 1.

	No audio cues	**Audio cues**
No visual cues	Group 1 (Control Group)	Group 2
Visual cues	Group 3	Group 4

Table 1: Mapping the treatment received by the 4 groups.

Efficiency. Efficiency is defined both as the amount of time it takes to find the topic of interest and the amount of cognitive load it requires for participants to process information. Because the MOA interfaces will provide users with a general overview of the linked page, such provision should help users find information of interest efficiently. As a result, it is expected that participants provided with the MOA Interfaces (Groups 2, 3 and 4) will spend more time reading and less time browsing than the comparison group (Group 1).

Effectiveness. Effectiveness is indicated by the participant's performance in recollection and comprehension. Fundamental to the interface design are the assumptions that: 1) the provision of an abstract will provide the users with a mental model about the content in the linked page; 2) elements in the abstract will prime and sensitize the users to the essential information to look for; and 3) information contained in the MOA interfaces could serve as a landmark in the information space. As a result, it is expected that participants provided with the MOA interfaces (Groups 2, 3 and 4) will perform better than the comparison group (Group 1). Moreover, among the three MOA interfaces, the hybrid MOA interface is expected to show the highest degree of effectiveness because two channels of the same message should have a reinforcing effect.

User satisfaction. User satisfaction is evaluated based on participants' self-report. Although the MOA interfaces will provide users with a facilitating mechanism to achieve the information-seeking goal, users may not be familiar with the given interface design. Therefore, it is expected that participants without MOA interfaces (Group 1) will provide higher scores on the measure of user satisfaction than the comparison groups (Groups 2, 3 and 4).

Interactions between usability components. In the current study, a negative correlation is expected between the measure of effectiveness and user satisfaction. This is because, while the MOA interfaces facilitate learning and comprehension, the unfamiliarity with the interface results in lower degree of user satisfaction.

More importantly, the current study will also find the redundancy principle of multimodality (Mayer, 2002) to be inapplicable. The redundancy principle argues that the incorporation of multiple modalities might have detrimental rather than beneficial impacts, when it is the same information being presented. It should be noted that most of the supporting research for the redundancy principle present contents in multiple modalities. Yet, content provided in the MOA interfaces are only to prime users with concepts to be covered; detailed information are provided in the same format across all four conditions in the current study.

Implications

One goal of the proposed study is to bridge the gaps between practices and research. While most recommended Web design guidelines are not empirically based, there has been lament about the lack of "usability" in educational research. The proposed study will set forth an example to address the given issues.

Findings also can provide evidenced guidelines for technology-based projects, such as distance-learning education and online libraries, concerning how multimodal presentations should be deployed and how cost-beneficial such practices could be. Moreover, results of the proposed project will also point to the fact that, when evaluating technology projects, it will not be sufficient to assess user satisfaction because usability is a multifaceted concept.

Abstract: The application of emerging digital technologies such as e-mail, the World Wide Web (WWW) and the Internet in the educational setting has received wide acceptance all over the world. Both corporate and academic agendas have recognized the potential advantages of e-learning; however, as a new field, e-learning comes with important issues that have yet to be tackled. Issues either pre-existing in the academic context, or stemming from the intertwinement of new technologies with the delivery and assimilation of education, minimize the effectiveness of e-learning implementations and therefore decrease the value perception of this practice. Such an issue is academic integrity and ethics. This paper attempts to identify ethical issues that concern the stakeholders involved, and stress the need for their consideration when implementing an e-learning course.

Keywords: E-learning, ethics, academic cheating, stakeholder theory

1. Introduction

Educational institutions have always been confronted with behavioural incidents that constitute ethical and moral implications among students, teachers and/or management. In order to deal with these implications, academic institutions proceed in the development of policies, regulations and disciplinary procedures. However, the introduction of Information Technology (IT) practices within the academic context has created a new set of questions considering value standards and ethics.

The cases of e-learning and distant learning are far more challenging, as physical presence and interaction are no longer required among students and educators. As all interactions are virtual, all academic standards, policies and regulations need to be re-examined, in order to constitute an e-learning course 'ethical'. Issues regarding equity, legality, privacy and justice stemming from political, social, cultural and economical implications need to be studied for the design and implementation of web based courses, as they have been in traditional educational practices (Athanasou, 1998).

The inquiry on ethics is the first and foremost task when evaluating an e-learning course (Athanasou, 1998). The consideration of ethical issues within such a course is as important as in any other educational setting. However, although most -if not all-academic institutions have formulated codes of ethics and teach ethics in their curriculum, little work has been done in e-learning so far (Stahl, 2002).

The purpose of our research is to identify ethical issues that need to be considered in the design and implementation of e-learning courses. Considering the socio-technical nature of e-learning, *stakeholder analysis* is employed as a tool to identify stakeholders, their relationships and potential ethical and moral implications within this context. More specifically, we have applied stakeholder analysis in three e-learning cases, and examined stakeholder interests and potential conflicts of interest that could trigger implications of ethical nature. Finally, we have proceeded in making some initial suggestions as to how our research findings can be used in order to formulate mechanisms for avoiding or/and dealing with such occurrences.

2. Education, IT and Ethics

Academic integrity has been under investigation for over a century. Cheating and plagiarism are two of the most popular 'unethical' practices students engage in (Philips and Horton, 2000). However, a mere 1.3% of students has been reported as 'being caught' (Haines *et al,* 1986 in Philips and Horton, 2000) from the 50% to 75% of students which admit having participated in some sort of academic dishonesty Baird, 1980 in Philips and Horton, 2000).

BEST COPY AVAILABLE

However, cheating is not the only ethical issue appearing in academic institutions. Issues such as gender or racial discrimination, as well as complaint procedures, disciplinary procedures, student responsibilities and rights are addressed in codes of ethics of universities. The introduction of IT has brought changes to how these issues become apparent. Also, IT has brought changes to the skills required, the roles of people involved, and the communication and interaction among students and teachers (Stahl, 2002; Watson, 2001; Schell, 2001). Therefore, changes must be brought to codes of ethics or the approach on ethical issues by academic institutions that employ IT in their facilities.

"Ethics is the philosophical study of the moral value of human conduct and the rules that govern it". Furthermore, ethics is mainly associated with specific people or groups of people that have social responsibility (L'Etang, 1992 in Grimshaw, 2001). Therefore, in order to apply ethical thinking in our context, it is important to identify the "groups of people that have social responsibility" in academic settings, and examine their position within the network of relationships and operations (Grimshaw, 2001, p.43).

3. Methodology

Ethics is a sensitive and delicate issue. It is a subject that concerns people's opinions and behaviours which can not be approached easily. Also, ethical issues often arise from hidden or unobvious agendas and are therefore difficult to spot directly. Another point that needs to be considered is that in the specific context of e-learning, ethical issues stem from the interaction of education and computing- hence human agents with computers. The socio-technical nature of e-learning implies that the investigation on ethics requires a wider frame of reference, and a need for employing special tools to our purpose. Stakeholder theory is a prominent approach to the examination of social networks, considered as a capable socio-technical tool.

Stakeholder theory is primarily used to identify stakeholders, their interests, and conflicts of interest, often with a moral perspective (Key, 1999). We therefore decided to apply stakeholder analysis to e-learning cases, aiming to identify stakeholder groups and how they and their interests are related within an e-learning environment.

The three cases used in our analysis, which will be described briefly later on, were documented using several techniques. The main process for getting input in our research was by taking interviews. About 20 interviews were conducted and recorded in order to provide the initial data for analysis. Additionally a number of documents were analysed including technical reports, deliverables, memos, e-mails and discussions. Finally a number of informal discussions contributed to our research.

Interviews are favoured because they allow the researcher the "best access to the interpretations that the participants have regarding the actions and events which have or are taking place, and the views and aspirations of themselves and other participants" (Walsham, 1995). An added benefit is that it allows researchers to step back and examine the interpretations of their fellow participants in some detail.

From the findings of the interviews and discussions, we have identified common issues within the three cases, which we have grouped and presented as being most critical. The reported issues should be considered both in terms of the analysis and design of the information systems, and the day-to-day practice of the learning/ teaching processes.

3.1 Stakeholder Theory

Stakeholder theory has been used extensively in the business context since the eighties (Key, 1999; Barrett, 2001; Papazafeiropoulou *et al.*, 2001). Stakeholder Analysis attempts to evaluate the role of actors in a firm's environment, as Freeman (1984) -considered to be the founder of stakeholder theory- suggests in his original work that both internal and external actors influence the organization's behaviour and performance.

There are various definitions of what a 'Stakeholder' is (Barrett, 2001; Papazafeiropoulou *et al.*, 2001). Freeman (1984, p. 46) defined a stakeholder within an organization as "any group or individual who can affect or is affected by the achievement of an organization's objectives". Another approach, provided by Clarkson (1995), describes stakeholders as:

> "*persons or groups that have, or claim, ownership, rights, or interests in a corporation and its activities, past, present, or future. Such claimed rights or interests are the result of transactions with, or actions taken by, the corporation, and may be legal or moral, individual or collective*" (p. 106).

The application of stakeholder analysis in an organization attempts to identify stakeholders, their claims, rights and interests, the transactions and relationships among stakeholders, as well as the moral and ethical "guidelines for the operation and management of corporations" (Donaldson and Preston, 1995). As the authors suggest, stakeholder theory has three main aspects: The descriptive, the instrumental and the normative:

- The *descriptive* aspect of stakeholder theory concerns the identification, description and possibly explanation of characteristics and behaviors of an organization.
- The *instrumental* aspect considers the identification of internal and external organizational connections.
- The *normative* aspect, where the theory attempts to elaborate on the function of the organization, and identify various moral and ethical issues that stem from the interconnections within the organizational network.

Ethical issues, as stated by Key (1999), are not considered in the traditional philosophical sense; rather, their identification aims at measuring the " 'fit' for utilitarianism" (p. 320), or, bringing to light the necessary trade-offs that need to be made between stakeholders' goals and the organization's goals.

Since the eighties, stakeholder analysis has found wide application in various contexts, such as the Information Systems (IS) area, and lately in the e-commerce area (Papazafeiropoulou *et al.*, 2001). Therefore, it seems appropriate that stakeholder analysis can be applied to e-learning cases, and perhaps assist in clarifying what issues need to be addressed in the design and delivery of an e-learning course.

3.2 Description of Cases

The proposition of theoretical directions for the case of elearning can be justified if empirical evidence can support conceptualisations that are not only descriptive but also incorporate and entail substantial practical implications. To this end, we have applied stakeholder analysis to three e-learning cases.

The case studies in our research are:

(1). The Global E-management Master (GEM) e-learning system and especially the T1 course entitled E-technology, which was delivered to the student of the GEM consortium. GEM provided expertise from an international e-learning implementation targeting on executives training with specific characteristics.

(2). The XEXO project (Educational space without limits), which objective was to establish an e-learning system and to deliver a master degree course to the students of three universities in Greece. XEXO was a joint effort of three well-known universities in Greece to design a common curriculum and to establish an infrastructure for e-learning.

(3). Finally, the Teleducation Center of Athens University of Economics and Business (TC-AUEB) which utilizes the WebCT platform in order to provide learning content to students. The TC of Athens University of Economics and Business, one of the biggest and well-organized universities in Greece with more than 8000 students refers to the implementation of an infrastructure for the delivery of e-courses, and the documentation of relevant services to educators and learners.

4. Applying Stakeholder Analysis to the three Cases

As mentioned before, we decided to perform stakeholder analysis to the three cases, compare our findings, and produce a generalized report on stakeholder groups, their interests and their relationships. This way, we could both gain more insights from multiple cases, and provide a set of issues which are identified in all cases, and are therefore most possible of appearing in other e-learning cases. Following we present a brief overview of the findings of stakeholder analysis in the three case studies.

4.1 Identification Of Stakeholders

Global E-management Master (G.E.M.)

1. The project manager
2. An e-learning specialist (webCT specialist)
3. An HTML programmer and a multimedia specialist that adopt the book oriented learning content to HTML pages with multimedia features.
4. Three content seekers, who based on general guidelines were searching internet, books and other sources in order to select content
5. Teachers in others Universities of the GEM consortium that would use the content in their teaching (in GEM same content is used in different universities)
6. A contact person for the facilitation of communication between development team and teachers in other universities

7. Students

XEXO project

1. The project manager, prof at the Technical university of Crete
2. Two project coordinators in AUEB, and Univ. of Macedonia
3. An e-learning specialist, owner of a company specialized in multimedia solution (Extreme media solutions S.A)
4. A content responsible for each course module, who worked according to the guidelines agreed by the committee constituted by (1, 2, 3)
5. An e-learning specialist for each course (webCT specialist)
6. An HTML programmer for each course module and a multimedia specialist that adopt the book oriented learning content to HTML pages with multimedia features.
7. A secretary who supported the project manager.
8. A help desk person who provided help at the pilot run of the system.
9. Students

Teleducation Center of Athens University of Economics and Business (TC-AUEB)

1. The Project Manager, a professor of the AUEB
2. The projects' scientific coordinator, an e-learning specialist
3. A project manager for each course that was developed (1,2 & 3 constitute a steering committee that is responsible for the specification and agreement on general guidelines).
4. A content responsible for each course, who evaluated the learning content in close cooperation with the teacher / content provider
5. An HTML programmer for each course and a multimedia specialist that adopt the book oriented learning content to HTML pages with multimedia features.
6. Two e-learning platform (WebCT) specialists, employees in the Teleducation Center) who facilitated the whole process of uploading learning content on content server.
7. A secretary who supported the project manager
8. A help desk person who provided help atthe pilot run of the system.
9. Students

4.2 Summary of Findings

Following the identification of key stakeholders in the three cases, we have proceeded in clustering them in 5 main categories, according to their generalized roles. In Table 1 we present the clusters of stakeholders that need to be examined. Following Table 1, we have proceeded in discussing their roles and interests.

CASE STUDY/ STAKEHOLDERS	GEM	XEXO	TC-AUEB
MANAGEMENT	Project Manager	Project Manager Project coordinators	Project Manager
CONTENT DEVELOPMENT	Three content seekers	One content developer for each module	Scientific Coordinator One for each course Teachers
TEACHING STAFF	Teachers	Teachers	Teachers
TECHNOLOGY RELATED STUFF	E-learning specialist HTML programmer Multimedia specialist	E-learning specialist HTML programmer Multimedia specialist	E-learning specialist HTML programmer Multimedia specialist
STUDENTS	Students	Students	Students

Table 1: Stakeholder Groups

1. **MANAGEMENT**: Overall, management issues regard adherence to deadlines and milestones, strategy, policy and meeting the implementation objectives.

   Project Manager: The Project Manager has an overall responsibility for *managerial issues* and performs all the necessary processes that secure the timely alignment to *timetable*. Deadlines, and project milestones are of critical importance. The ultimate objective of this stakeholder is a well functioning elearning system that has *meet the implementation objectives* through the establishment of flexible control managerial mechanisms.

Institution Policy Maker: In business environment or in academic environment this person has an overall authority to determine or to *influence the strategy* and the consequent *policies*. Concerning elearning this person influences the importance that is paid to e-learning implementations since in many cases e-learning is recognized as of limited importance and an evangelist is required in order to transform this opinion within organization.

2. **CONTENT DEVELOPMENT:** This stakeholder group is concerned with developing the content to be taught to students.

   Content Author: The main concern of this stakeholder group is to provide content that meets the standards that have been specified by the Scientific Coordinator, or have been agreed by a correspondent committee. In many instances the limited experience in e-learning is a main obstacle for his performance since the majority of content providers have a book-oriented perspective, which in e-learning becomes boring.

   Scientific Coordinator: This stakeholder pursues a two-fold goal. Firstly he has to align good *practices of e-learning* in specific implementation and secondly to demand for *high quality learning content*. Of course the alignment of good practices implies a number of issues such as collaboration, motivation, active participation, ethics, etc.

3. **TEACHING STAFF:** This stakeholder group is *managing the learning process* through the capabilities of the e-learning platform. He has in mind a learning scenario and a personal way of teaching which in many times tries to simulate in e-learning through technological capacities.

4. **TECHNOLOGY RELATER STAFF:** Implementation of the system is the main concern of this stakeholder group.

   E-learning platform specialist: This person is the critical *connector that stands between content provider and learner*. The performed utilization of e-learning platform's capabilities requires the establishment of a common language between content author and e-learning platform specialist. In some cases authors do not know what an e-learning platform offers

   Technical Manager: A technical manager has an overall responsibility for all the technical aspects of the implementations concerning e-learning platforms and other applications necessary for the development of content. He justifies economical proposals of technology providers and according to several criteria proposes solutions to the project committee or the project manager.

   Multimedia & HTML specialist: They are responsible for the preparation of learning content and the transformation of hard copy material to electronic learning modules. Their work has often bottlenecks since have to wait for content from authors or content providers.

   Technology Provider: The technology provider has a product to sell and he tries to convince the project manager or the scientific coordinator that his solution is closer to project needs.

5. **STUDENTS:** This stakeholder group is either forced or willing to participate in an e-learning course. The main interest of students is the assimilation of knowledge and the acquisition of the degree or diploma the course presumably provides. Very often he is disappointed from the static content of html pages, which are the containers of learning content in e-learning implementations.

4.3 Stakeholder Relationships

Following the identification of stakeholder groups, we illustrate how they are interrelated within the e-learning network (Figure 1).

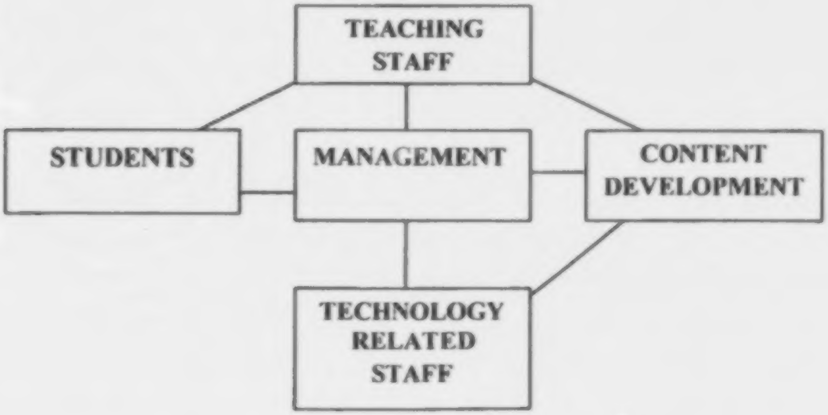

Figure 1: Stakeholder Relationships

5. Ethical Issues in e-Learning

In a recent study on the role of codes of conduct in ethical behavior in academic institutions (Rezaee *et al*, 2001), the authors project the main issues that codes attempt to deal with. It should be noted that the issues discussed concern traditional academic institutions, and not e-learning environments. The most common issues are:

- Conflicts of interest
- Compliance with university policies
- Faculty grievances
- Administrators, faculty and staff performance
- Confidentiality of proprietary information
- Tenure and promotion policies and procedures
- Financial fraud
- Allegation of fraudulent conduct in research or scholarly procedures

Other ethical issues discussed in literature are integrity, equality, economic efficiency and equivalence (Tucker *et al.*, 1999), as well as security and privacy (Stead and Gilbert, 2001). All the presented issues need to be re-examined for e-learning environments. However, as discussed earlier on, academic fraud is the most problematic ethical issue in the academic agenda; for this reason we will elaborate on this issue further.

5.1 Academic Cheating

Dealing with the issue of cheating is not an easy task. It requires efforts regarding both academic and technological interventions. Due to the nature of the e-learning environment, these efforts need to take place from the design of the system and course rather that making adjustments, if they are to be mostly effective. Furthermore, these efforts regard various stakeholders, as we shall see further on.

Philips and Horton (2000) have suggested four 'strategies for monitoring and discouraging cheating':

1) Continuously update topics for projects and avoid 'classics'
2) Promote group effort
3) Police the internet for potential violations
4) Develop a well thought-out set of policies and regulations regarding cheating

Indeed, these four strategies should be able to promote a more ethical pattern for e-learning practices. However, the role of technology within these considerations is very critical. In order for the preceded propositions to be mostly utilized, they should be considered primarily in the design of the system, while keeping in mind the stakeholders and their interests as proposed in the findings of the stakeholder analysis. Following we apply the suggestions of the two authors to the stakeholder groups we have identified.

Continuously update topics for projects and avoid 'classics'
By achieving this, it should make it more difficult for students to find reusable assignments, either from previous academic terms, or from the internet.

This task regards primarily the TEACHING STAFF stakeholder group. They will be required to always be current, and continuously look for new topics while searching for similar topics available on the web. However, this task does not only depend on TEACHING STAFF, but CONTENT DEVELOPMENT as well. Teaching material should also be updated and new events or e.g. case studies should be incorporated.

Promote group effort
Group effort can minimize cheating to a great extend. Apart from creating a 'moral obligation' towards other group members, it also reduces the possibility of actually having a whole project done by someone else, unless the whole group decides to do so. It would also be sensible to change groups often, based upon random choice of members.

Having such a strategy is a matter of MANAGEMENT, as well as the stakeholders involved in the previous proposition. However, this task requires certain technological applications that promote online collaboration, which would therefore require the involvement of TECHNOLOGY RELATED STAFF.

Police the internet for potential violations
Although it might not seem as the most preferable strategy, it is necessary to do so. Submitted assignments should be checked on the web.

Develop a well thought-out set of policies and regulations regarding cheating
Before all, it is necessary to consider all possibilities that can potentially arise, develop a set of regulations and procedures and make everyone aware.

This is an issue of the MANAGEMENT to develop the set of policies and regulations. However, CONTENT DEVELOPMENT STAFF, TEACHING STAFF, TECHNOLOGY RELATED STAFF and even STUDENTS should not be kept in isolation during such a task.

Apart from the four strategies discussed by Philips and Horton, there are a few other suggestions:

- Ethics should be included in the curriculum of every course. Students should be taught ethics, not only for the sake of academic ethical behavior, but professional ethics as well. Ethical awareness is perhaps more important than a new code of ethics (Doost, 1997).
- Surveillance techniques should be established for e-learning. Technological advancements should be incorporated in e-learning applications that could, to a certain extend, monitor students.
- Research should be conducted in the matter of what causes unethical practices. Crown and Spiller (1998) suggest individual and situational factors that lead to cheating, such as age, gender, religion and previous education. Such work should also be done for e-learning, which would help in best understanding how to avoid and/or deal with unethical behavior.

6. Conclusion

"The G.E.M. degree will displace classical marketing, accounting and law studies with e-commerce versions. There is a strong belief that this is essentially what a regular MBA will look like in five or six years" (Brin, 1999 in Stead and Gilbert, 2001). Indeed, in terms of quality of course content, delivery, and overall practice, G.E.M. and other e-learning cases may well be of high standards. However, in order for e-learning to establish a stronghold alongside traditional university education, social factors need to be considered equivalently.

It has been noted that ethical issues are not given the necessary attention in e-learning implementations, as they do in traditional formal educational practices. Although these issues arise from the application of new technologies in the educational context, the subject is not purely technological, but merely a matter of the design and delivery of the service, whilst considering the changes in the delivery and assimilation of education that e-learning technologies bring about.

In our paper, we have conducted a stakeholder analysis and identified the following stakeholder groups in an e-learning environment: Management, Teaching Staff, Content Development, Technology Related Staff and Students. After a presentation of their generalized roles within an e-learning environment and their relationships, we have proceeded to the presentation of various ethical issues addressed in academic environments, and, with a focus on the issue of academic cheating, reflected various proposed strategies on the identified stakeholder groups. By doing so, we have generated a clearer picture of how one issue concerns all the stakeholder groups in an e-learning environment. Also, we can see how stakeholder interests are interrelated and therefore where potential conflicts of interest reside.

We believe that if e-learning opts to grow of equivalent respect to traditional education settings such as universities, ethics and morality are of the primary issues to be considered. In this paper, we have initiated a discussion regarding the issue of ethics in e-learning environments, with a focus on academic cheating. However, a more in-depth analysis is required in order to generate considerable input for the design of such an information system. Finally, as Colette (2001) suggests, in order for e-learning systems to be successful, they must be designed and constructed with care, using scientific procedures and techniques. In turn, this calls upon ethical responsibility and professionalism in the design and development of an e-learning system.

Science Education in the Web Era

Leon L. Combs, Ph.D.
Department of Chemistry and Biochemistry
Kennesaw State University
Georgia, USA

I. Introduction

Education has entered a new era and there is considerable uncertainty among higher education administrators and faculty about how to proceed. Of course, the web era started some years ago, but education does not quickly accept the need for change, and reluctance to quickly adopt possible new methodologies is sometimes wise. Some institutions have tried quickly introducing online courses and many of them have failed to meet expectations. Other institutions seem to be attempting to ignore that we are in a new era and that a new format is available to help students reach a new level of understanding of subject matter. Several new companies have come into existence to offer the expertise to allow universities to quickly develop distance education programs using the web, and some of them have disappeared. As we proceed along the time line of the web era of education, it seems that perhaps some combination of what has seemed to work in the past, and what new techniques seem to work now is the best approach. This combination approach we will call the hybrid approach. In developing such a hybrid approach, what we need to do first is to establish how, in this new web era, we should proceed to help our students learn to the best of their abilities.

I. Education Technique

I hope that every educator in every discipline would say that we want our students to learn to think creatively as they learn. A method proven to enhance creativity is the learning theory of constructivism (Elizabeth Murphy, 1997; C. Fosnot, 1996), which is based on the philosophy that learners should actively construct knowledge in their attempts to understand their universe. Educators using this method want the students to have an opportunity to use their prior knowledge and senses in making connections to the new concepts introduced. Educators also want the students to be able to explain a new set of data based upon the new concepts they have understood. Therefore, if one accepts that constructivism is the route to choose for the basis of our educational philosophy, and if we admit that we are in a new web era of education, we must ask "how can educators use technology to guide the constructivist approach to science education?" The discussion here is not the first study of the use of technology in constructivism (Perkins, D). In addition, others have discussed constructivism in science education (Anthony Lorsbach and Kenneth Tobin, 2000). However, this paper will attempt to answer that question for education in the sciences, and with techniques explicitly applicable for today's web format. We will begin by addressing some pertinent questions for education in this new era.

II. Questions and Answers

A. What is Education?

Since about ten years ago, it has been said that information has been doubling every five years. Given this rapid rate of development of information, what then does it mean to be educated today? In addition, what does it mean to be well rounded in education? Since information is changing so rapidly in all fields, it is only the truly exceptionally bright and mature person that can continue to be considered knowledgeable in more than one discipline. Everyone has to be a life-long learner or be hopelessly behind the information curve early in life. People can't continue to just stay in school all their lives, so they must learn to learn on their own and the web affords an excellent venue for such education. Of course, just because a topic is presented on the web does not necessarily mean that the information is current or even correct. Therefore, there is a need for some sort of accreditation of web sites for correct information, and that presents the need for some group of knowledgeable people that spend time checking and validating web sites. Organizations such as the American Chemical Society could use retired faculty members to periodically review such sites and provide some seal of acceptability for the site. We would stress the tremendous need for some sort of validation of knowledge base on the web sites.

B. Where is the classroom?

This discussion leads us to asking, "Where does the student receive education?" Such a question can have different answers depending upon the status of the student. Since we all must be students all of our lives, there are two categories of students: those without a degree, and those with a degree. This article will not develop the inquiry about what a degree will be in a few years! [Nevertheless, just for thought, in the future perhaps instead of a "degree" there will be standardized exams for people to take to prove the attainment of a certain level of current information.] However, regarding the classroom, it seems that there will continue to be a need for classroom instruction for some years in the future. There still are many students without the necessary learning skills and self discipline to learn complex topics completely on their own. Many of these students will continue to need the classroom and the live instructor to help them develop an acceptable understanding of the disciplines. However, we are convinced that an extremely promising method of successful teaching in this web era is a hybrid approach of web-enhanced classrooms. Other people are coming to similar conclusions (Jeffrey R. Young, 2002). Universities currently actively investigating this hybrid model include Fairleigh Dickinson University, Pennsylvania State University, Harvard University, the University of Central Florida, and the University of Wisconsin system.

C. Where are the students?

The next logical question is "where are the students?" and, based upon the discussion above, we think that the answer is that they will be on the campus and anywhere. We believe that the demand for completely online courses will increase in the next few years, and probably increase more as students from the high schools become more adapted to self-learning as their teachers begin to also use a hybrid approach.

However, it seems that educational institutions must be ready to serve students both on campus and online.

D. What do we teach?

Now we are led to the next question "what do we teach?" Do we teach material from a textbook? Do we teach material from the world (ideas, concepts, and information developed since a textbook has been written)? Since information is increasing so rapidly, especially in the sciences, do we continue to use a written textbook? The answer probably depends upon the level of the course. For introductory mathematics, chemistry, and physics, the written textbook is probably "safe" for a few more years regarding the need for some means of presenting fundamental concepts. The textbook companies have been supplementing the textbooks with videos and demonstrations on CDs for several years. One company (Thinkwell) is now marketing a web/CD combination for a substitute for the standard written textbook, and we will be experimenting with such at this university in some chemistry and mathematics courses the fall of 2002.

E. How do we teach?

The next question to be answered by educators is "how do we teach?" The answer could be a formal lecture style, discovery based with classroom small group interactions, some combination of these first two possibilities, the first two with web supplement, or completely web-based. We think all of these methods need to be used in the modern "classroom". As mentioned before, there will be an increasing number of students with the necessary skills to learn completely from a web site and such web sites need to be available for these students. We believe that such web sites should be developed based upon the web components required for various learner styles. Such a methodology of web course development will be published in 2002 (Leon L. Combs, 2002) and so will only be briefly reviewed next.

III. The Web Course

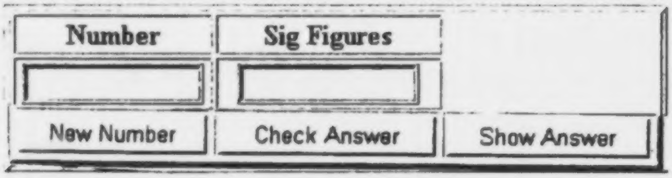
We must never try to fit pedagogy to technology. We must always have firm learning goals for the web course and use the technology that best enhances the learning experience. The web course must have a process for evaluation and assessment built into it from the development stage, and it must have a design for stimulation of interactivity among the learners. Frequent activities must be required as well as recurrent student reflection. The site must be interactive from the beginning and this can be accomplished using simulations, online quizzes, java-based repetitive exercises for acquiring needed knowledge, discussion groups using electronic bulletin boards, submitted assignments, and frequent proctored testing. Video is needed for the visual learners and such presentations can be done with streaming video from the web site or, probably preferably for the next few years, presented on accompanying CDs. Animated gifs can sometimes substitute for a short video. Slides with audio discussions are effective learning tools and can be easily developed with Real Slideshow.

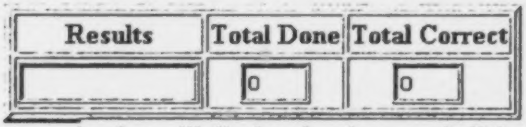
Everybody's role changes for a web course, for the teacher is now a tutor and a facilitator, and the students are independent learners. The facilitator must create the environment, guide the process, moderate the process, manage the content, and create a learning community among the learners. The teacher should give a learner style pre-test for all learners to help the teacher and the student better understand what is needed for that particular learner to best proceed.

The reader can go to http://ChemNet.kennesaw.edu and from that site choose from among four courses in freshman chemistry for examples of web courses in chemistry. These web sites were designed by utilizing web components corresponding to the following learner styles: visual, auditory, read/write, kinesthetic, sequential or global, inductive, deductive, active, and reflective. It should be stressed that there is a need for only web site for each course, so faculty members need not fear that all of them are going to have to develop such a course. Every course should have one web site that is easily accessible to the learners. Every faculty member can then used the web site in whatever hybrid manner is best for their course and their teaching philosophy.

IV. The Web Advantages

Every student of science must develop basic understandings that require repetitive practice to make sure that the concept is understood. One such concept is significant figures and the web can provide that assistance by the use of sites that look like the following



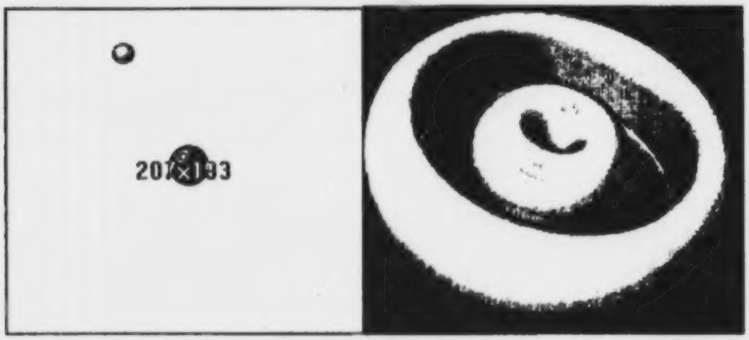


Results	Total Done	Total Correct
	0	0

The student goes to a site that will display the above and clicks "New Number" so that a number like 0.047249 appears. The student enters the number of significant figures for the number in the next space provided and clicks "Check Answer" to determine if he/she was correct. This process needs to be repeated, as new numbers will cover all types of numbers requiring a thorough understanding of significant figures for correct answers to be obtained. This same sort of repetitive testing can be done with many concepts such as moles, molarity, molality, the periodic table, quantum numbers, etc. Upon completing these web site testings, the student will know how to use these concepts. This site (http://proton.csudh.edu/lecture_help/lechelp.html) has many such testings.

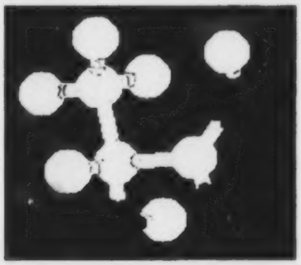
BEST COPY AVAILABLE

Another area in which the web excels is in the use of animations and simulations of abstract concepts such as the Bohr and quantum mechanical model of the atom.



In this animation the student can click on one of the orbits and cause the yellow ball (electron) to change orbits and the student will see if energy will be given off or if it is must be supplied. Since the Bohr model is not correct, the student can click on a particular orbit and see the corresponding quantum mechanical illustration of the probability of where the electron is as seen to the right above. Such animations and simulations can be developed for many areas of the sciences and are of tremendous help in the learner developing a deeper understanding of the concepts. In such simulations, variables can be changed and the student will immediately see the result and determine if the result was what was expected based upon the understanding of the theory. If the result is not what the student expected then he/she must develop a better understanding of the theory (constructivism).

Another important web application is being able to click on the structure of a molecule and rotate the molecule in any manner desired. Such an application gives the student a better understanding of the three-dimensional structure of the molecule than any two-dimensional representation. Below is lactic acid as it could appear on the web site except that you have to imagine that you can click on it and rotate it in any direction.



Imagine a course web site containing discipline information; online comprehension quizzes; electronic discussion boards; and many such repetitive testing, animations and simulations, and diagrams that can be rotated as noted above, and we begin to understand the huge advantage that the web has to offer education in the sciences.

BEST COPY AVAILABLE

V. Conclusions

The web era offers educators a very rich venue for expanding our educational methodologies. A few minutes spent on a web search will show web applications in many disciplines. Particularly in science, the web-enhanced classes can greatly enrich the experience of the learners. We have comparison testing results showing that students in web-enhanced chemistry classes consistently score higher on standardized exams that the students in the traditional lecture style classes. Other data collected by following students through advanced classes also suggest that students retain the understanding longer than students in traditional classes do. The conclusion is that we are in a wonderful new era of education: the web era. At this point in the era, it seems that the most promising direction for universities to pursue is the hybrid approach of using the web material as a supplement to the still-evolving classroom structure. This era is developing so fast that conclusions reached today could be invalidated tomorrow.

However, it does seem that the web-enhanced class is the method of choice today, and that universities need to be developing web-based instruction in all disciplines for the short-range purpose of enhancing the classes. Commercial organizations such as Thinkwell are already developing such enhancements, and it may be that outsourcing to such organizations is the most practical way for universities to proceed at this time. Since many universities use the phrase "life-long learners", they need to be helping students develop the skills, resources, and desires to learn how to properly use the web for life-long learning.

Towards a Standards-based Approach to e-Learning Personalization using Reusable Learning Objects

Owen Conlan, Declan Dagger, Vincent Wade
Trinity College, Dublin,
Ireland.

E-mail oconlan@cs.tcd.ie, daggerd@tcd.ie, vwade@cs.tcd.ie

Abstract: e-Learning systems that produce personalized course offerings for the learner are often expensive, both from a time and financial perspective, to develop and maintain. Learning content personalized to a learners' cognitive preferences has been shown to produce more effective learning, however many approaches to realizing this form of personalization involve considerable re-authoring of existing learning material. To reduce the implementation overhead on the content author and course designer it is imperative to facilitate the maximum reuse of learning resources.

This paper investigates a standards-based approach to delivering personalized learning content to learners using WWW technologies. Detailed is an implementation of a personalized eLearning service, called the OPen Adaptive Learning Environment (OPAL), which is based on delivering content personalized to the learner's cognitive and presentation learning preferences using aggregation models based on ADL SCORM (ADL).

INTRODUCTION

Mechanisms that facilitate the reuse of learning content allow course authors to increase the life span of the content they develop. As these are often expensive and time consuming to develop the potential for any reuse should be maximized to achieve maximum return on investment. There are a number of factors that increase the potential reuse of learning content –

1. Granularity of the content
2. Effective and descriptive metadata
3. Appropriate packaging of the content and metadata for distribution

These factors, however, do not directly improve the pedagogical quality of the content produced. Learners have been shown to respond well to content and education systems that adapt to their personal preferences. The key to this process is an appropriate learner model constructed either explicitly through an online instrument or implicitly through the learner's interaction with the learning environment.

This paper details an approach to content authoring and packaging that enables the course author to create learning content that is both reusable and capable of supporting different pedagogical approaches through a content aggregation model. Section two details content issues such as packaging standards and granularity, section three shows how content packaging can support some approaches to adaptivity, section four discusses techniques for modeling the learner, section five covers the OPAL Environment and section six gives a summary of the paper.

PACKAGING LEARNING CONTENT

Packages of learning content and associated descriptive metadata are produced to facilitate the portability of learning content between different Learning Management Systems (LMS). The packages usually contain additional information about how the amalgamated learning content should be sequenced and additional metadata that describes the learning resources.

As the learning content, from which the content packages are built, may be stored in searchable repositories, with appropriate metadata, the course author may simply have to search for pre-authored material and combine it into a new offering. This is the model adopted by the EASEL IST project (EASEL) were a basic semantic registry and learning resource repositories were constructed to facilitate metadata searching across multiple schemas.

By re-sequencing the learning content in the package or by adding additional content or by adding content that supports different approaches to learning the course author may produce additional packages tailored to specific learning approaches and learner prior knowledge, while still supporting a common learning objective in the different course offerings. For example, the author may produce three packaged instances of a course, each tailored for a different level of prior knowledge from prospective learners. A simple knowledge pre-test instrument may be used to determine which package is the most appropriate for each individual learner.

Multiple content packages may be aggregated together to assemble an aggregated content package. This enables a learner's requirements to be met from more than one package.

Content Granularity

The size and scope of the pieces of learning content that are combined to form the content packages is a key consideration. For example, if a content package is comprised of only a few pieces of large grained learning content then re-sequencing them to form a new package that supports a different pedagogical approach may not be possible, as the new narrative flow may not make sense in the context of the learner's learning. This issue is paramount in the reuse of any learning object (Conlan et al. 2002).

To facilitate reuse learning objects should be fine-grained, paragraph or diagram size, for example. Content packages should be used where larger grained learning resources are required as they may be constructed using smaller learning resources and/or other content packages. Both IMS Content Packaging and ADL SCORM facilitate the assembly of content packages by combining other content packages or assets, such as in the case of SCOs.

With smaller grained learning objects the course author has greater flexibility in the creation of additional content packages. For example, if learning objects are available at the paragraph level then the course author can add/remove content at this level to produce tailored courses.

Candidate Standards

IMS Content Packaging IMS Content Packaging is an interoperability specification to allow content creation tools, learning management systems and run-time environments to share content in a standardized set of structures. Version 1.1.3 of the specification is focused on defining interoperability between systems that wish to import, export, aggregate, and disaggregate packages of content (IMS CP).

The primary goal of the IMS Content Packaging specification is to provide a mechanism which, once implemented by producers and vendors, will allow content to be exported between systems with the minimum of effort. Version 1.1.3 of this specification is currently available as a public draft.

ADL SCORM In 1997 the United States Department of Defense (DoD) and the Whitehouse Office for Science and Technology Policy (OSTP) set up the Advanced Distributed Learning (ADL) initiative to push development plans for standardization of Learning Resources. Their standardized approach to creating cross-compatible systems and content is encapsulated in their Sharable Content Object Reference Model (SCORM) (ADL). The SCORM constitutes three key components –

- The Content Aggregation Model (CAM).
- The Run-Time Environment (RTE).
- Content Packaging.

Through these components the ADL aims to meet the high-level requirements of –

- **Reusability**, content persistence over different LEs. A unified method of content markup.

- **Accessibility**, globally accessible content repositories. Metadata search facilities.
- **Durability**, learning resource and system component persistence over time.
- **Interoperability**, create systems and learning resources that are operation system and platform independent.

The purpose of the Content Aggregation Model (CAM) is to provide a common gateway for the composition of learning content from discoverable, reusable, sharable and interoperable sources (ADL). The CAM describes the Content Structure Format (CSF). The CSF allows standalone learning resources to be aggregated into either a complete course or a section of a course. Also described are mechanisms that facilitate the movement of content between different LMSs and repositories.

The three components described by the SCORM CAM for use in building reusable content are –

1. **Assets** A primitive representation of learning content, e.g. an applet, flash animation, image etc.
2. **SCO (Sharable Content Object)** Represents the finest grained learning resource traceable by the LMS e.g. a collection of one or more assets. A SCO should be system independent, i.e. should contain a compatible launch sequence persistent across multiple SCORM compliant LMSs.
3. **Content Aggregation** Involves the virtual mapping of SCOs together to form cohesive units of instruction that can be delivered to the learner through the SCORM Run-time Environment. (ADL)

Through the SCO (Sharable Content Object) markup the content may be described using an XML binding based on the IMS Learning Resource Metadata (IMS LRM) specification XML Binding. This specification has been extended as part of the EASEL IST Project (EASEL) with descriptive elements to facilitate the description of adaptive material (Conlan et al. 2001).

Describing the Content

The reuse of learning resources is aided considerably by appropriate, descriptive metadata accompanying the resource, enabling the content author to assemble new course offerings from existing content. If the metadata used to describe these resources is compliant with a known standard the reuse of the learning resources is extended beyond the bounds of the initial course delivery system.

The XML binding for extended IMS Learning Resource Metadata (Conlan et al. 2001) can be used to describe particular attributes of the content to which a system may adapt. For example a piece of content may include in its metadata –

```
<adaptivity>
        <adaptivitytype name="learningstyle.vark.visual">
                <candidate>4</candidate>
        </adaptivitytype>
        <adaptivitytype name="learningstyle.vark.auditory">
                <candidate>2</candidate>
        </adaptivitytype>
        …
</adaptivity>
```

This XML snippet describes a piece of content that rates quite highly on the visual scale of VARK (Fleming 1995),(Bruen & Conlan 2002). If the learner's profile is built using a similar mechanism then the LMS will have a framework in which to compare the learner with candidate content.

ADAPTIVE TECHNIQUES

There are many adaptation effects that may be supported and facilitate using content packaging. Most of these techniques have their origins in Intelligent Tutoring Systems (ITS) and Adaptive Hypermedia Systems (AHS). The most effective uses of content packaging to provide adaptivity, however, involve situations where learning content re-sequencing or replacement produce course offerings that differ to large degree in pedagogical approach.

Curriculum Sequencing Curriculum sequencing is an adaptive technique that can produce very effective differences in how learners perceive learning content. Pedagogical theories such as Kolb/McCarthy place great emphasis on how content is sequenced and the ways different learners react to that learning content.

Content packaging allows a course author to produce several *versions* of the same course, each sequenced in a different manner. For example, one version of the course may start with a case study and derive the theoretical aspects of the material from that study. While another may start with the theory, present some examples and finish with a self-assessment quiz.

The effective production of these different versions assumes that the constituent parts of the packages are sufficiently small-grained that they may be re-sequenced. There may be a need to author some additional narrative content to facilitate the different routes through the content the individual content packages offer.

Contextualization When courses are being offered to corporate learners it is often desirable to use case studies and examples that pertain to those student. For example, if you are offering a programming course for accountants a course that uses accounting examples will be more familiar to the students. If the examples used are individual *grains* of content then that same programming course may be offered to civil engineers by simple changing the example learning objects for more appropriate examples. In this way content packages may be used to store several versions of the same course that differ only in context.

MODELING THE LEARNER

A learner/user model contains explicitly modeled assumptions that represent the characteristics of the student which are pertinent to the system. The system can consult the user model to adapt the performance of the system to each student's characteristics. User modeling allows the system to personalize the interaction between the student and the contents. To achieve effective learning this personalization should put the content in a context that the student can understand and to which they can relate. There are several techniques for modeling the student and refining this model.

The Stereotype Model Creating fixed stereotypes is one of the simplest ways of user modeling (Rich 1989) . New students are categorized and the system will customize its performance based on the category that has been set for the student. A common example would be the notion of novice, intermediate and expert users within a system. This approach is useful when a quick but not necessarily completely accurate assessment of the user's background knowledge is required (Kobsa 1993).

The Overlay Model The overlay model is widely used in the adaptive hypermedia systems in the educational domain. A model of the student's knowledge is constructed on a concept-by-concept basis and updated as the user progresses through the system. This allows for a flexible model of the student's knowledge for each topic (Brusilovsky 1996).

For this model the knowledge domain must be modularized into specific topics or concepts. The complexity of the model depends on the granularity of the structure of this domain knowledge and the granularity of the estimation of the student's knowledge. This estimation is build up by examining the sections the student has read and the test he has performed.

The Combination Model The Stereotype and Overlay techniques of user modeling are often combined in educational adaptive hypermedia systems. The student may be categorized by stereotype initially and then this model is gradually modified as the overlay model is built from information acquired from the student's interaction with the system.

There are a number of implicit approaches that may be used in acquiring and refining the user model. These include –

- The observation of the users direct-manipulative interaction with the software system.
- The analysis of the information which the user retrieves from a database or repository (Kass & Stadnyk 1992).
- The system can also explicitly ask the user for information (Kobsa 1993) employing mechanisms such as questionnaires and tests.

Learner Model Standards and Specifications

Candidate Learner Model specifications include PAPI (PAPI) , IMS Learner Information Package (IMS LIP) and the GESTALT (GESTALT) user model. As yet none of these specifications deal with the representation of pedagogical aspects of the learner, such as learning styles, prior knowledge or life long learning goals (i.e. career path). Even if there was a recognized standard for passing this information there is no common vocabulary to which AHSs could adhere to process the information. Individual AHSs will however have their own mechanisms and vocabularies for storing pertinent learner information.

PAPI PAPI (PAPI) is the IEEE Public and Private Information Specification which is a standard format for the representation and communication of student profiles. The purpose of the specification is to allow the creation of student records which can be communicated between educational systems over the lifetime of a learner.

The profile information,for a learner is divided into four areas - Personal information which is for private consumption such as the student's name, address and Social Security Number; Preference information which may be for public consumption, such as the technology available to the student, the learning style of the student, physical limitations or disabilities. This information is collected with the cooperation of the student, i.e. it is negotiated; Performance information which is for consumption by technology. This consists of the observable behavior of the student and may include grades, reports and logs.

The PAPI specification also incorporates the Dublin Core metadata element set. The information used to construct the user profile is inferred by the system, directly input by the user or is constructed by the user and system in collaboration. PAPI also intends to address the privacy and security issues involved in the storage and communication of user profile (PAPI) .

IMS Learner Information Package The IMS Learner Information Package (IMS LIP) specification addresses interoperability between internet-based learner information systems. Learner information concerns Learners (individual or group) or Producers (creators, providers or vendors). LIP includes facilities for the Learner to determine which aspects of their information are sharable with other systems. LIP has been designed with four basic requirements in mind –

- Distributed Information
- Scalability
- Privacy and Data Protection
- Flexibility and External References

The last requirement is described in (IMS LIP) as Learner information includes many constructs, such as learning objectives and learning history, which are in practice represented by different structures in different contexts. Learner information data models must be flexible enough to accommodate this need. IMS LIP v1.0 is currently available as a public draft.

GESTALT GESTALT (Getting Educational Systems Talking across Leading Edge Technologies) (GESTALT) which is funded by the ACTS project, is an educational environment for online learning which extends the IMS metadata definitions. A user profile is constructed from information acquired from the user by asking the user to complete forms displayed by a wizard. The user model is created as an XML document which is then stored physically on the user's machine. The profile information stored includes the user's educational history and technology available to the student.

Some of the profile details acquired include personal details, contact details, qualification details, skill details, learning preferences and mode of delivery. The learning preference is stored as a boolean value of 'Yes' or 'No'. The user profile is created as an XML document that will be stored physically on the user's machine.

Modeling Cognitive Preferences

VARK (Fleming 1995) This technique of learner modeling uses a concept of multi-modal learning strategies, where the student being modeled does not have an outstanding preferred mode of learning but instead uses a combination of two, three or even four of the styles.

For example, one student may prefer a combination of the visual aspect and the kinesthetic aspect, to produce a comfortable learning experience for them. Another may prefer an aural, read-write combination for their learning environment. In rare cases students being modeled score evenly across all four spectrums.

Kolb/McCarthy Kolb's learning style model categorizes learners on two continuums, *abstract/concrete* and *active/reflective*, based on personal preferences for the consumption of new information. It suggests that the learner should cycle through all four styles in order to gain a full understanding of the topic.

The overview of this model is to present the learner firstly with their preferred style of learning, based on the two continuums and then cycle through the other 3 modes.

Bernice McCarthy has applied the original model set out by Kolb to categorize learners in accordance to the different cycles as follows.

1. Innovative Learners: *concrete/reflective*.

   This learner prefers to be shown the practical applications of the new material being presented.

2. Analytic Learners: *abstract/reflective*.

   This learner prefers to be presented with the results of research and well ordered sequential presentation of new material

3. Common Sense Learners: *abstract/active*

   This learner is a "try it and see" learner. Provide guided activities and keep them updated on where they are in the content.

4. Dynamic Learners: *concrete/active*

   This learner prefers the ability to explore other sources of information on the relative topic, hyperlinks to those resources.

THE OPAL ENVIRONMENT

The design approach of the OPAL (OPen Adaptive Learning) Environment architecture follows, in many ways, that outlined in the SCORM documentation specification. This approach has a central *repository* of content remotely stored on a database. The job of the Learning Management System is to access this data, display it to the learner in a coherent manner, and track their progress through the material.

System Components

Figure 1, below, shows the main components of the OPAL environment. The functionality of these components is implemented using twelve Java Servlets, through which the learner interacts with the system. The OPAL Environment is an LMS supporting learning resources that are descriptively tagged by SCORM metadata. The OPAL environment uses SCOs as the basic unit of content storage. The environment has some additional functionality that enables it to perform adaptivity at the level of content packages and at the content delivery stage by employing stretch-text type methods to selectively hide or remove individual types of content.

This mechanism is implemented by the key servlets –

- **AHSQuestionnaire** This servlet queries the learner, by delivering an appropriate online instrument to them and assembles the returned answers from which the learner profile is built.
- **LMSAddNewLearner** This servlet is responsible for authenticating the learner and selecting appropriate SCOs (content packages) to deliver to the learner as a content aggregation model (CAM).
- **LMSCourseServlet** This servlet accesses the CAM and determines how the SCOs should be assembled and the first SCO to be delivered to the learner.
- **LMSDisplaySCO** The LMSDisplaySCO servlet is responsible for the delivery of the content from the different SCOs in the CAM to the learner.

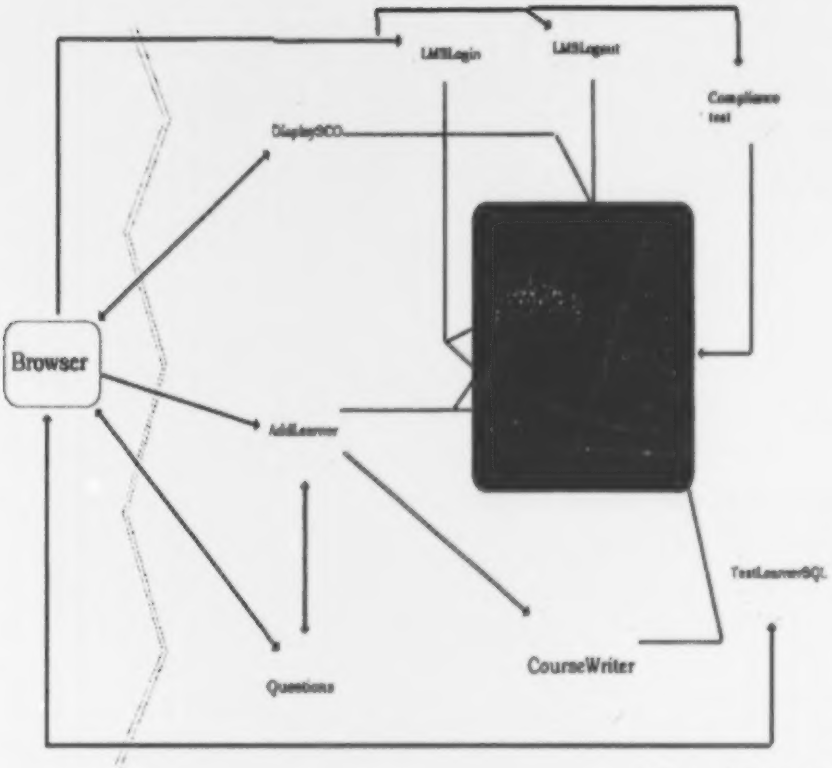

Figure 1: System Components

Building the Learner Profile

The AHSQuestionnaire servlet is responsible for building the learner model and adding it (using the LMSAddNewLearner servlet) to the profiles repository in the system. The model is determined explicitly by querying the learner. For example, in the case of the VARK (Fleming 1995) model the learner is asked 36 simple questions to build a profile of their visual, auditory, read/write and kinesthetic attributes. Once the questions are completed the results are returned to the LMSAddNewLearner servlet where the values are interpreted. This interpreted profile is stored in the profiles repository.

Building the Personalized Course

There exists only a finite number of SCOs in the content repository and it is the role of the LMSCourseServlet to assemble the SCOs selected by the LMSAddNewLearner servlet into a course offering tailored to the learner's profile with a personalized navigation structure. A selection process is initialized based on the learners' profile. This process induces an aggregation model for the learner based on their existing profile. The learning resources' metadata could also be used in this process. This metadata may be described in the manner section 2.3 Describing the Content. Once the servlet has identified the appropriate aggregation model it assembles the content, ready for delivery. This course structure is persistently stored in the course_table in the LMS repository.

BEST COPY AVAILABLE

Delivering the Personalized Course

It is the role of the LMSDisplaySCO servlet to display a personalized navigation structure to the learner around the selected SCOs. This servlet presents the learner with a simple next/previous navigation buttons for changing pages within the SCO as well as textual links to those pages. Also provided to the learner are links to other sections (other SCOs) and to a course index. This navigation structure is built by examining the structure of the SCO and its constituent learning content.

SUMMARY

This paper describes an approach to developing personalized e-Learning content using content that is reusable both in an adaptive and static manner. The key to this reuse is appropriate metadata and the use of content packages.

Also described was the OPAL Environment as an implementation of an adaptive e-Learning system based on SCOs. As in most Adaptive Hypermedia Systems the cornerstone of the personalization process is the building of an appropriate learner profile. This profile is induced to a selection process to assemble a personalized course for the learner.

A New Tool for Managing Students Self-Evaluations in Traditional and Distance Education Courses

Juan Contreras-Castillo, Arthur Edwards Block

Facultad de Telemática Universidad de Colima, México

Abstract

This paper describes a web-based question-answering system called E-teacher that can be used in both traditional and distance learning courses to review academic contents. E-teacher is a self-editing template-based system which consists of a set of PHP scripts that generate the HTML code dynamically, or "on the fly." The entire E-teacher is managed through an ACCESS database located on a Web server and data are stored and recovered upon request. E-teacher was developed to assist students review course content and reinforce the knowledge gained during traditional or distance learning courses. E-teacher will be piloted in English courses offered at the Facultad de Telemática of the Universidad de Colima.

Introduction

Since the early 90's teachers have recognized the potential of the World Wide Web (WWW) as an instructional tool (Crossman, 1997). As a consequence of this, they have created different types of educational materials to be exploited on the WWW, including text documents, multimedia presentations, etc. Unfortunately, this medium (online teaching) does not allow interactivity with instructor and class materials in the same manner as face-to-face contact permits. Even though the importance of these types of interaction (student-contents and student-interface) has been highlighted by Moore (1989) and Hillman (1994). This shortcoming often represents a major disadvantage when reviewing class content for self-evaluation purposes; because as Barker (1994) mentions, interactivity in learning is a necessary and fundamental mechanism for knowledge acquisition and the development of both cognitive and physical skills.

With this difficulty in mind, we developed a prototype of a Web-based question-answering system, called E-teacher, to complement online and traditional courses in facilitating students' self-evaluations and review course materials.

E-teacher is a template-based system which is managed though an ACCESS database (http://www.microsoft.com), where data are captured and retrieved upon request. The system will be integrated into distance education courses offered by the Facultad de Telemática of the Universidad de Colima (FT), in Colima, México (http://telematicanet.ucol.mx). E-teacher is composed of nine activities that can be used as independent modules or in combination and can be easily integrated within online courses

E-teacher will be piloted by English as a Second Language (ESL) professors at the FT as a complementary tool in their face-to-face courses. The implementation of this Web-based question-answering system will make student self-evaluations and the interactivity with the course materials easier and more efficient. In contrast to other simple strategies for handling student questions, such as bulletin boards, newsgroups, listservs, and e-mail, this system has a set of modules to increase the interactivity of students with course materials. For instance, E-teacher has a module that rates the performance of each individual student, based on random exercises and exams for their personal use without recording any data about the results. The activities for students within this system and their full descriptions are listed on table 1.

Activity	Description
WordScramble	The system randomly misarranges the letters within a response, which students must appropriately order to reproduce the correct answer.
SentenceScramble	The system randomly misarranges the syntax of a sentence or phrase, which students must appropriately order to reproduce the correct answer.
MatchCols	The system produces two columns which students must correctly correlate.
Fill	The system produces sentences or paragraphs with spaces which students must complete with the correct response.
SingleChoice	The system produces multiple choice questions with between two and ten options with a single correct choice.
MultiChoice	The system produces multiple choice questions with between two and ten options with an equal number of possible correct choices.
Dialog	The system misarranges elements (dialogs, processes, etc.) within two columns which students must correctly order.
Random	The system accesses the database of the type of exercise the student chooses (Fill, MatchCols, etc.) to randomly produce exercises from all the categories contained within that specific database.
Exams	The teacher selects a maximum of 20 questions from the 7 different question-type databases (Fill, MatchCols, etc.). Students then select any number of practice tests the teacher has previously captured.

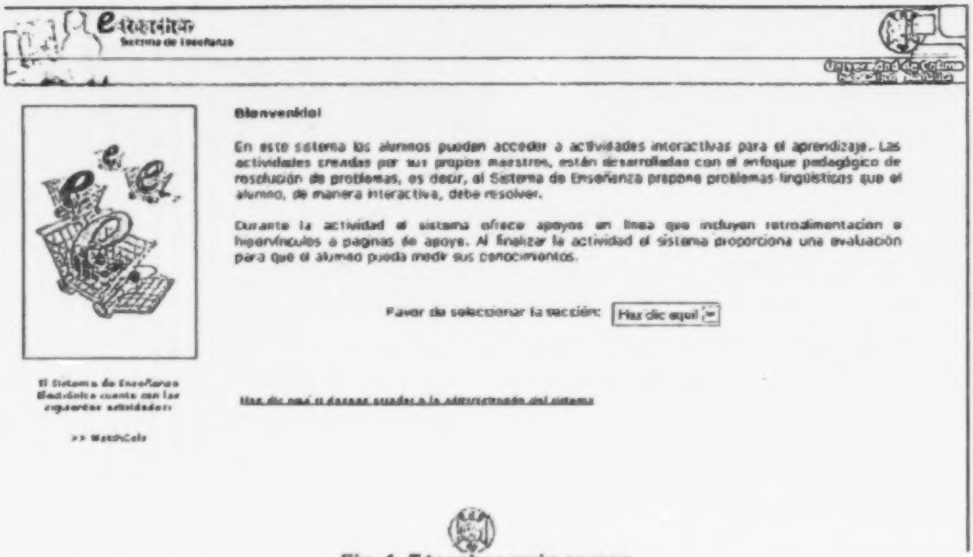
Table 1. Different type of activities on e-teacher

Description of the question-answering system

The E-teacher system consists of a set of PHP files that generate all the HTML code dynamically. This PHP code handles all the operational tasks. The files reside in an Apache Web Server operating in a Windows 2000 server with a PHP module version 4.0. In addition, the system is also installed on a pc running under the Linux operating system. The database that handles all the files can be accessed transparently through ODBC in any platform that supports this open database connectivity. The system consists of student, teacher and administrator modules.

The E-teacher is an open system for students. Any student can access the system to review course materials independently of the topic or teacher. Teachers, however, must be registered by the system to add, modify or delete review materials. In figure 1. we show the main screen for the E-teacher system.

It is important to mention that students can not modify the contents, graphic interface or functionality of the system. This can only be done by the teacher(s) who possess the access code previously authorized by the administrator of the system.



Bienvenido!

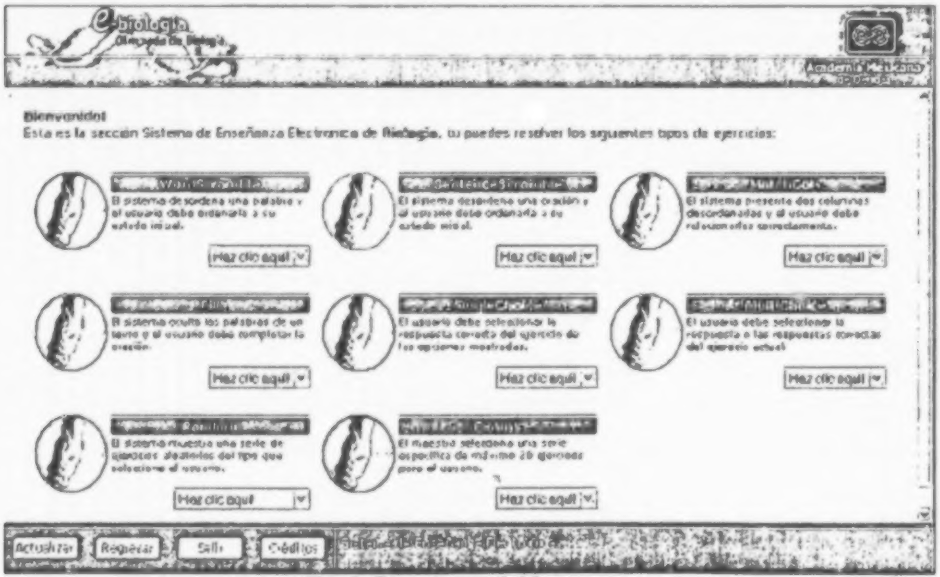
En este sistema los alumnos pueden acceder a actividades interactivas para el aprendizaje. Las actividades creadas por sus propios maestros, están desarrolladas con el enfoque pedagógico de resolución de problemas, es decir, el Sistema de Enseñanza propone problemas lingüísticos que el alumno, de manera interactiva, debe resolver.

Durante la actividad el sistema ofrece apoyos en línea que incluyen retroalimentación e hipervínculos a páginas de apoyo. Al finalizar la actividad el sistema proporciona una evaluación para que el alumno pueda medir sus conocimientos.

Favor de seleccionar la sección: Haz clic aquí

Fig. 1. E-teacher main screen

In the main screen, students can select the review material they want to access. As a test, we offer two different courses, English and Biology. Once they select the review material, the activities screen for that material is displayed as previously personalized by the teacher. This is shown in fig 2. In this Figure the topic the student selected was Biology. Once the student accesses the activities page, he can select among the options the instructor has previously developed (the different options are mentioned in table 1), as well as the individual exercises or exams he wishes to practice. Again, as a test we offer review material about the Cell. Within each activity, students have several standard and optional selections. Each of the standard options and its description is listed in table 2. In table 3 we list the optional selections, depending on the additional information teacher wish to provide.



Bienvenido!

Esta es la sección Sistema de Enseñanza Electronica de Biología, tu puedes resolver los siguientes tipos de ejercicios:

Fig. 2. E-teacher activities screen

BEST COPY AVAILABLE

Option	Description
Menu	Returns students to the activities main screen.
Instructions	Provides specific instructions on how to resolve the item
Review	Provides feedback about the degree of accuracy of the response
Next Item	Provides student with a new item
Resolve	Provides the correct response.

Table 2. List of standard selections for students.

One important characteristic is that teachers can provide students with several levels of difficulty depending on whether or not they wish to incorporate the optional selections. Teachers can incorporate these options in the teachers' main screen. Table 3 shows the different optional selections available to teachers:

Option	Description
Hint	Presents additional information to assist students resolve the item
Tip	Offers the next correct step needed to solve the item
Lesson	Provides a hyperlink to relevant pages related to the contents of the review material.

Table 3. List of optional selections for students

In figure 3, we show the SentenceScramble activity to review material about the Cell. In this activity, students have to select the correct word and place it in the correct syntactic order. As they order the phrase, they can ask the system for help, pressing the "Hint", "Tip", or "Resolve" buttons. Depending on how many times they press these buttons, the system calculates an average score for each answer and, upon finishing the activity, provides a total score.

Conclusions

The fast and increasing development of distance education courses via the World Wide Web has made the development of computer systems that increase the interactivity of students-contents and students-interface necessary. With this goal in mind, we have developed a system based on a set of PHP scripts and templates to help students review materials and to realize self evaluations with a high level of interactivity with the course content. It is our hypothesis that this system will help students increase their cognitive and physical skills on the material they review.

BEST COPY AVAILABLE

To prove this, our future work, will consist in piloting the system with several English as a Second Language courses that are taught at the Facultad de Telemática of the Universidad de Colima in México to evaluate the system within an actual educational context and determine any possible improvement in the development of language skills in first year students.

In addition, we are also considering the addition of a new student-student, teacher-student interaction module that will permit students in online courses to interact among themselves and help increase the community feeling for this type of courses.

Abstract: This paper reports on considerations about the common basic functions and components for building a collaborative authoring environment. We aim to specify and systematize the technological issues towards the future standardization of such environments, based on our previous research experiences. Standardization includes many difficult aspects, however it will extend and widen the field of applications possible within the collaborative and cooperative authoring paradigm, and will enable the usage of the fruits of years of research and individual implementations of the concept of collaborative, but mostly, cooperative authoring. In this paper, we try to set a systematic basis for a common collaborative authoring platform.

Introduction

Cooperative and collaborative authoring (C^2A) are fundamental authoring forms that become more important with the paradigm shift towards re-usage and cooperation in the current authoring technology. The objects of C^2A are the *collaborative mutual interdependence* relations and the *group-implying activities* (Okamoto et al 2000; 2001).

Simply put, in pure *collaborative authoring*, each author takes over (an) authoring sub-task(s). When each author accomplishes the sub-task(s), the group goal is reached and collaborative mutual interdependent authoring is achieved.

In the wider spread *cooperative authoring*, authors just re-use each other's materials, (teaching) style, learning goal settings, dictionaries, linking and sequencing, etc.

Distributed C^2A is a type of collaborative authoring that can take place in the network environment, etc., with multiple authors virtually far from one another (comparable to the situation in O'Malley 1994). A virtually distanced setting can mean remote physically (geographically), but also covers cases where direct interaction and dialogue among participants is not possible due to other reasons. Distributed C^2A support is a pioneering research domain that tries to find out ways to support the cooperation and collaboration (C^2) of multiple authors on the network.

Computer Supported C^2A (CSC^2A) is directly connected to distributed collaborative learning (CSCL - Computer Supported Collaborative Learning) (ISO/IEC), in cooperative curriculum-related activities, according to the used Learning Technology (IEEE LTTF), on one hand, and to CSCW (Computer Supported Cooperative Work) (Conklin & Begeman 1988; Malcolm & Crowe 1994; Winograd & Flores 1986) on the other. Compared to CSCW, CSC^2A has the same direct goal, i.e., *working efficiency*, in the sense of authoring achievement efficiency combined with the recognition or meta-recognition of the subject field. At the same time, CSC^2A has as a final goal *the student learning* *achievement efficiency*, borrowed from CSCL (Dillenbourg 1999; Okamoto et al 2001).

The regular CSC^{2}A-management software implementation should provide therefore two types of activity space: a *private working space* and a *collaborative working space*. The first is, unlike in collaborative learning (Okamoto et al. 2001), just a space for processing the material into a final form, to be copied into the collaborative space. In pure collaboration this private space practically disappears, as authoring becomes an iterative, peer-feedback dependent process. Here, authors can exchange information in a synchronous, but mostly, asynchronous manner. Many researches are studying these two types of activity spaces for learning environments (Okamoto 2000; Okamoto et al. 2001;Synnes et al. 1999), but not enough studies focus on authoring purposes. We now propose to analyse the case of the C^{2}A Environment (C^{2}AE) (Cristea et al. 2001), by mapping it over the previously proposed collaborative learning environment case (Okamoto et al. 2000) and extracting analogies.

CSC^{2}A can be organized at many levels, starting with the selection of the appropriate knowledge representation and inference mechanism (Dicheva et al. 2002). Our current paper goes one step further and focuses on the interaction activities, the structural model they imply and the interfacing of these structural component objects. As this framework is aimed at covering the need of coordination and facilitation of authors working together towards one/more common/disjunctive authoring goal(s), we use the adjective 'collaborative' for describing both objects and activities, as being more powerful and restrictive than its counterpart, 'cooperative'. Mainly, if collaboration is possible, cooperation results implicitly. Moreover, by removing some of the features and restrictions, the collaborative environment can become a cooperative one.

Primitive Activities and Required Resources in C^{2}A

In this section, we describe the primitive interaction activities among participants in C^{2}A, from a macro-granulation perspective. From a technological viewpoint, every CSC^{2}A should provide appropriate tools ensuring a flexible, viable selection of these activities. Here we list them in their order of priorities: *Planning/ Execution/ Creation; Coordination / Control; Initiative/ Supervision; Observation / Suggestion; Data / Idea sharing; Dialogue (with Interaction).*

Surprisingly, compared to collaborative learning (Okamoto et al. 2000) only *Turn Taking* doesn't appear as a primitive activity, and supplementary to pure Execution, *Creation*, as a higher level execution form - implying new knowledge addition - appears. To perform these activities, the following resources are required in C^{2}A environments: *Personal Workplace; Shared Workplace (shared object space); Dialogue Channel (implicit or explicit); Technologically mediated remote communication (audio, visual)* – latter optional for cooperative environment. Furthermore, more refined cognitive tools are desirable for facilitating group collaborative authoring, such as, e.g., concept mapping tools (Cristea et al. 2001), etc. Therefore, we consider that an essential condition for CSC^{2}A systems is that the common platform/ infrastructure should have at least the above-mentioned resources built-in.

Figure 1: The Global Structural Model of the Cooperative and Collaborative Authoring Environment

BEST COPY AVAILABLE

Figure 1 displays the C^2A concept from the point of view of the author behavior and the resource usage. We can differentiate between *author-to-author dialogue* (communication) and *other activities* (curriculum creation, etc.).

Note that we include the coordination activities in the latter category. The figure shows the layers for the C^2A goal and C^2 work, as well as the layer containing the various authoring resources to consult during C^2A. These include all possible resources to which the author has access during authoring in an Internet environment (e.g., authoring materials, all-purpose tools, specialized tools, authoring applications, various authoring data, etc.).

In C^2A an author can face an authoring task that s/he doesn't have either time or personal resources to fulfill and, by interactions with other authoring companion(s), or by consulting other materials, can exchange meaningful information and notice other ways of perception and teaching. As authoring efficiency has been shown to increase in C^2A situations (Dicheva et al. 2002), some systems try to encourage collaboration and especially re-usage with the help of computer implementations.

C^2AE Structural Components

Collaborative Authoring Model Elements

Figure 2 shows more details and various essential elements of the conceptual image of the C^2A model, where workplace and working subjects are brought together. Authors can belong to one or more groups, or none at all (pure re-usage, i.e., cooperation) and can be involved in curriculum creation projects or parts of projects together, therefore sharing that particular space (pure or partial collaboration) and work privately for the rest.

The C^2A shared (collaborative) workplace contains *dialogue support objects* for information exchange support, *collaborative work & goal objects* for authoring related support and the *collaborative memory*, for reference and information and end-product (course, etc.) accumulation (Fig. 2).

The private workplace contains the *work & goal repository* of the private working objects and the *private memory* for consultation and accumulation of information on private activities, notes, etc.

Moreover, the figure also details the information referencing layer that is shown to contain information oriented towards individual and collaborative authoring goals, authoring materials, various educational data, libraries, educational applications, all-purpose tools, market applications, etc.

Please note that both workplaces (private and C^2) are part of the respective workspace. In an analogy with the traditional classroom, we could say that, for a learning environment, the classroom itself is (part of) the collaborative workspace, while the collaborative workplace contains the blackboard, which is accessible and visible to everyone (and has a certain access policy, determined by the teacher agent).

C^2AE Structural Elements

There are six essential basic structural elements (objects) for building the C^2A environment. Due to lack of space, only the first hierarchical layer of definitions will be presented in this article.

1. C^2AE Representation: Many systems have already used the collaborative learning paradigm (Okamoto et al. 2000) and helped towards extrapolating the important structural points of a C^2AE (Fig. 1,2). To define the C^2AE, we need to define the following six concepts: *General structural model of the C^2AE; Essential structural elements of the C^2AE* and their *Attribute(s)* and *Relation(s); Dynamical model of the C^2AE (data transmission model); Dynamical mechanism of the C^2AE (data exchange mechanism).* These are shortly described in this paper.

2. Collaborative Workspace Representation: The collaborative workspace is an essential structural element of the collaborative part of the C^2AE that establishes a virtual space for collaborative activities for authoring groups and collaborating individuals, and ensures the continuity of these collaborative activities within that space (by activity related information recording, etc.). Moreover, this space also provides functionalities for the cooperative activities. The workspace definition requires the definition of the following terms below: *Structure of C^2A workspace*, its *Essential elements* and their *Attribute(s)* and *Relation(s).*

3.Authoring Resource(s) Representation: C^2A resource(s) have to be guaranteed for private activities, collaboration (screen sharing, operation sharing) and cooperation (repository sharing). Here we need to define: *Essential structural elements of the C^2A resource(s); Fundamental referencing model of resources* (e.g., Dicheva et al. 2002).

4. Collaborative Workplace Representation: The collaborative workplace belongs to the *collaborative workspace*, and is an essential component of the C^2 working environment, used in groups for collaboration, or, with respect to the outer world, in cooperation. Namely, the collaborative workplace is in a "use_of" relation with the group and the private author. This workplace is determined, as already mentioned in the previous sub-section, by the *collaborative communication (dialogue) support objects* for distant group members, by *C^2 work & goal objects* and by the *collaborative memory* that uses both previous object types for storage and retrieval. The defining of the collaborative workplace requires the definition of the terms below: *Collaborative workplace structure*, its *Essential elements* and their *Attributes* and *Relation(s).*

5. Collaborative Author Group Model

The group is defined within the collaborative workspace of the collaborative authoring environment. The group uses the collaborative workplace and pursues the collaborative authoring goal. This goal is defined as a set of individual achievements expected from the multiple members of the group. To define the author group model, the following elements and terms must be defined: *Group model structure*, its *Essential elements* and their *Attribute(s).*

6. Collaborative Memory Structure Representation

The collaborative memory (CM) is included in the collaborative workplace of the collaborative workspace. It serves to store the objects used for dialogue support and objects used and developed in C^2A. Moreover, it has the role to retrieve these objects and stored information at request (later on, the CM or a copy of it will have to respond to requests in relation with learning). To define the collaborative memory structure, the definition of the following terms is necessary: *Collaborative memory structure*, its *Essential elements* and their *Attribute(s)* and

Relation(s).

C^2AE Data Transmission Model and Interface Objects

Data Transmission Model in the C^2AE

Figure 3 shows the data transmission model in a C^2AE populated with authors and author group(s). The C^2A support system has to be able to send and receive, at the author's request, essential information regarding the C^2 and private workspace elements. Figure 3 illustrates our hypotheses by displaying a minimum of required relations. For example, a function has to be built that is able to fetch C^2 or private work objects requested by the group or privately from various resource(s), here represented by the *load_into* relation.

Interfaces

Five interfaces for the common objects can be defined, as briefly described below.

1. Interface between Authoring Resource(s) and C^2 Work Object(s)

The group performs collaborative activities by loading the C^2 work object(s) of the collaborative workplace from the authoring resources, for group and personal use. Authoring resource(s) are used by multiple groups or individuals. By activating a group request, a memory image of the requested authoring resource(s) is produced, and therefore the collaborative work object(s) of the group collaborative workplace come into being. For defining this interface and its regulations, the following must be defined: *Authoring resource(s) reference structure*, its *Essential elements* and their *Attribute(s)* and *Relation(s); Protocol between the authoring resource(s) agent and the collaborative work object agent.*

2. Interface between Dialogue Support Object(s) and Collaborative Work Object(s)

The dialogue support objects enhance the information exchange between authors and manage the communication activity history. The role of the communication among authors is to support and smoothen the various authoring activities managed by collaborative work object(s). Namely, the communication that takes place in order to achieve the group-authoring goal is closely related to communication in collaborative work for problem solving. For the computer to understand the meaning of the communication, it is necessary to link the output of the dialogue support object and the collaborative working object (proper ontological representation). For this purpose, the items below need to be defined: *Dialogue support object and collaborative work object output data structures*, their *Essential elements* and *Attribute(s)*.

3. Interface between the Private Workspace and C^2 Work Object(s) of the Collaborative Workplace

C^2A does not always take place in the collaborative workspace. A group member or an independent author can bring in work results from the author's private workplace to the collaborative workplace, or the work result from the collaborative workplace can be copied to the private workplace. Therefore, next to the definition of the C^2 work object input data, the definition of the output data of the private workplace is also necessary, as follows: *Private workplace output data structure*, its *Essential elements* and their *Attribute(s)* and *Relation(s)*; *Protocol between the private workplace agent and the collaborative workplace agent*; *Protocol between the collaborative workplace agent and the collaborative work object agent*.

4. Interface between C^2 Work Object(s) of the Collaborative Workplace and the Collaborative Memory

The C^2 work object output data is the authoring log data. The interface uniformity between the C^2 work object(s) and the collaborative memory within the collaborative workplace is ensured by the C^2A log exchange and the C^2 work object addition/deletion. By establishing a uniform representation of the C^2A log, the accumulation in and the reference to the collaborative memory can be implemented in an interoperable form. For this, the items below must be specified: *Relation between the essential elements of the collaborative workplace structure and authoring log structure*; *Storage request structure of the authoring log into the collaborative memory*, its *Essential elements* and their *Attribute(s)* and *Relation(s)*; *The reference request structure of the authoring log from the collaborative memory*, its *Essential elements* and their *Attribute(s)* and *Relation(s)*.

5. Collaborative Memory - Group Model Interface

The collaborative memory of the collaborative workplace stores various data developed during the group curriculum activities. This information is the ordered and managed information of the group model. Thereafter, the group model is registered. When some new group activity commences, the previous activity history and results from the group model are referred. Moreover, the collaborative memory stores data developed during public individual authoring activities. Therefore, the collaborative memory maintenance is necessary. For the correct reference of such information, the items below have to be defined: *Relation between the collaborative memory attribute(s) and the group model attribute(s)*; *Relation between the collaborative memory attribute(s) and the (independent, individual) author model attribute(s)*; *Output data structure from the collaborative memory into the group model and individual author model*, its *Essential elements* and their *Attribute(s)* and *Relation(s)*.

Data Exchange in the Collaborative Authoring Environment

Virtual Agent in the Collaborative Authoring Environment

One of the essential structural elements of the collaborative authoring environment is the virtual agent (as in learning environments – see Paiva 1996).

The information exchange between the other essential structural elements can be done via agent(s). The attribute(s) of the appropriate essential elements are stored in the collaborative memory as well as the authoring log developed during collaborative authoring. Furthermore, depending on the request from group member(s) and collaborative work object(s), agents refer the information in the collaborative memory and integrate the exchanged information into a defined form. The concrete function of agents is to cope with the behavioral differences of the essential structural elements. Moreover, the information exchange protocol content varies, according to the transmission source and reception destination, and according to the behavior or functions of the bi-directional structure of the essential elements. Therefore, agents are dynamic interfacing structural elements. However, the basis functions of the agents in the collaborative authoring environment are defined simply as the exchange, deletion, addition of essential structural elements.

Collaborative Authoring Agent

The technological issues to specify for the agents delimited by the above assumptions are represented by the 5 items below.

1. collaborative authoring environment agent(s) structure
2. collaborative authoring environment agent type(s)
3. essential elements of the collaborative authoring environment agent(s) structure
4. attribute(s) of the essential elements of the collaborative authoring environment agent(s) structure
5. relation(s) of the essential elements of the collaborative authoring environment agent(s) structure

Conclusion

The technological concept formation of the basic and common platform for building the cooperative and collaborative authoring environment (C^{2}AE) needs a collective effort and is an ongoing process. We have started in this paper from some considerations based on our experiences, and have gradually built specification items towards a future standardization. We have not followed the ramifications we have opened due to lack of space. To give just a flavor of next developments necessary, we mention here some further functions required by the C^{2}AE (Okamoto et al. 2001):

- *Coordination* (constrained and mediated by the external environment)
- *Reification* (material evidence in the external environment)
- *Illustration* (external representation)
- *Storage* (in later use, for the purpose of reflection)

Examples of general tools for supporting collaboration are as follows: *Concept Mapping tools; Editors for argumentation network; Work flow* (planning tool); *WYSIWIS* (What You See Is What I See). So far, we have integrated a few parallel projects with related goals (distance learning, life-long learning, re-usage of educational materials), under the name RAPSODY (Okamoto 2000) and RAPSODY-EXT (Okamoto & Cristea 2001).

In this paper, we have systematically elaborated, from an academic point of view, the fundamentals of the common functions and components for building a platform for a C^{2}AE for the future directions of standardization. However, these considerations and issues are only the first steps towards standardization, and our paper doesn't claim to be exhaustive on the matter. For further research, the presented standardization candidate items have to be refined further on, and their functionalities extended. Therefore, we need more investigations and discussions to persuade people about the importance of standardization for collaborative and cooperative authoring.

By using a common architectural, functional and technological basis and, moreover, by using other common concepts not treated in this paper, such as a common ontology for a static representation model, and a common dynamic model (e.g., in Petri net representation), real collaboration and cooperation within authoring environments for learning environment creation can be achieved.

ODL Education Environments based on Adaptivity and Adaptability

Alexandra Cristea and Paul De Bra
Technische Universiteit Eindhoven
P.O. Box 513, 5600 MB Eindhoven
The Netherlands
{acristea,debra}@win.tue.nl

Abstract: In the Information Society of the new millennium, the use of Information and Communication Technology (ICT) is becoming essential for the rapid dissemination of information. In this context, Open and Distance Learning (ODL) will have a growing role in effectively training people to have active roles in society. However, modern learners have a variety of backgrounds, with respect to knowledge, social environment, preferences, etc. Therefore, our main goal is to create the basis of a European platform of standards for user modeling-based adaptability and adaptation, towards individualization of the learning process. This paper reports about the birth of a new European project, ambitiously aiming at going one step further than plain user modeling (UM), by creating a common structure for the ODL systems' adaptive response to specific user needs, thereby creating a basis for modern European Education. The main goal of this paper is to highlight the importance of the standardization of the adaptive and adaptable techniques to the research community at large, and therefore find more external support for our efforts. Moreover, this paper presents some first background research to establish a starting point for this project.

Introduction

The society of the beginnings of the new millennium is also known as the new Information Society. Information and Communication Technology (ICT) is becoming increasingly essential for the information dissemination, and especially, for knowledge dissemination. With such premises, Open and Distance Learning (ODL - Blair 2000; Cristea & Okamoto 2001; Nkambou et al. 1998) has a growing role in effectively training people to have active roles in society, as a precondition of fostering a real equality among them. The main problem with ODL, noted by many researchers (Brusilovsky 1996; 2001; Marshall's University CIT; Oppenheimer 1997) is that it offers monotonous, uniform education to everybody.

However, with this expansion of the reach of education and creation of equal opportunities, as well as with the need of giving practical expression to the principle of lifelong learning, the need of handling cultural and linguistic differences, gender differences, the analysis of learners' attitudes and profiles, is increasing.

Our main research objective is to establish a *European platform of standards (guidelines, techniques and tools) for user modeling-based adaptability and adaptation*, in the sense of the new paradigm of intelligent human-computer interaction, based on the new generation of ODL tools, towards individualization of the learning process. Note that similar standardization efforts exist, for e.g., collaborative learning (Okamoto & Cristea 2001; Okamoto et al. 2001), or the Semantic web research, but in the area of adaptivity and adaptability there are no real efforts towards some unification of means and methods. In other words, the semantic web creates the basis on which the adaptivity and adaptability standards can be built.

Our two year long project's main contribution will be to go one step further than plain UM (Learner Model IEEE LTSC; Rich 1979), by creating a common structure for the ODL systems' adaptive response (Wu & De Bra 2001) to specific user needs, thereby creating a basis for modern European Education.

Motivation & Objectives

As previously stated, this project's main objective is to establish a European platform of standards for UM-based adaptability and adaptation, using methods and techniques of, among others, artificial intelligence (Cristea & Okamoto 1999) and neural networks (Cristea & Okamoto 1997), towards individualization of the learning process.

More concretely, the following objectives will be pursued:

***O1.** Identify a set of relevant good practices of (UM based) adaptation techniques for education; based on current technology.*

***O2.** Extract a minimal set of relevant and necessary features for adaptation techniques in education and for distributed (Internet) and multimedia environments.*

***O3.** Extract a supplementary set of relevant (but not necessary/ essential) features for adaptation techniques in education; also extract examples of irrelevant features (redundant techniques sets).*

***O4.** Based on O1-O3, define guidelines (minimal set of requirements) for an authoring system for adaptive techniques in education.*

***O5.** Build a prototype adaptive authoring tool [0] and, separately, one (or more) training system(s) based on the minimal set of relevant features, with possible addition of supplementary features.*

***O6.** Evaluate the adaptive prototype system on different target groups.*

O7. Disseminate and promote the results.

Target Beneficiaries

The primary beneficiaries of the project and research outputs are:

- *Students* of a large variety of disciplines that can profit from the pursued trans-disciplinarity and knowledge individualization envisaged by the project.
- *Teaching staff* from the institutions *participating in the project*, who can use the researched techniques for their own courses.
- *Researchers* in these disciplines, who will have a unitary basis to work upon.
- The larger *research community*, which can benefit from these results and will be able to integrate them into their own research.
- The *standards community*, which will be able to use our standard proposals.
- *Teaching staff at universities outside the project* that want introduce adaptive methods in their teaching.

Adaptability vs. Adaptivity

Adaptability

The lowest level of "intelligence" for the WWW is to have some adaptable features. I.e., *the user* (learner or teacher/ course designer, in our case) *can make some options that will determine some alterations to the aspect, contents or functionality of the Web material.* The simplest example is to have a button for changing colors. Another, more complex example, is to have alternative courses for students with disabilities: for instance, to read aloud the material for visually impaired students – or to simply provide a version with larger characters.

We group these static adaptable features under the name of adaptability.

Adaptivity

Adaptivity, on the other hand, is what one would expect from this term: *the actual capability of the system to adapt automatically to the new conditions* (usually deduced from a user model). This represents a more advanced step towards artificial intelligence, compared to adaptability.

In the following, some insight into the fundamentals of these techniques will be given. Adaptation and adaptability are approached here from the perspective of the person to whom the web site has to adapt to (or be adaptable for): the user. Both adaptation and adaptability can exist without UM. An example where this sometimes occurs is adaptive hypermedia (Brusilovsky, 2001). For the purpose of the project, all these aspects will be studied. However, the more personalized a website has to become, the more the *user model* and *UM* grows in importance (Fink et al. 1997).

For the purpose of this paper, we will therefore analyze some fundaments of user modeling. A more sophisticated model has to take into consideration the learner's cognitive styles – in this case, learning styles.

Adaptation Granularity

Another aspect to consider in doing user adaptation is the granularity of this adaptation.

- At the lowest level there are *direct adaptation techniques*, such as *adaptive navigation support* and *adaptive presentation*, as described by (Brusilovsky 1996), and implemented by such adaptive hypermedia systems as AHA. These techniques are usually based on threshold computations of variable-value pairs. They can be considered as the *low level adaptation techniques*.
- At a next level, we can envision more goal-oriented, or at least, domain-oriented adaptation techniques, based on a higher level language that embraces the primitive low level adaptation techniques (and serves as a wrapper to the former). These new techniques can form an adaptation language (as developed in Calvi & Cristea 2002), and can be considered *medium level adaptation techniques*.
- Finally, at the last level, we can include adaptation strategies, embracing and wrapping the layers above. These strategies are goal-oriented, although the same strategy could be, generally speaking, used for different goals. This layer is the *high level adaptation layer*.

In the following, we will shortly sketch some of the higher level features that can be included in adaptation techniques.

Learning Styles

The literature provides various definitions of cognitive styles (proposed initially by Allport in 1937) and learning styles (proposed initially by Herb Thelan in 1954), and often the two terms are used interchangeably. For our purpose, we are focusing on learning style, as the specific individual approach of each student to new knowledge acquisition (Cristea & Okamoto, 2001a). According to the student's learning style, the student is able to receive knowledge easier or not via a certain teaching style. The learning style is independent from the other abilities, which have direct sequels (the more, the better – Pham), whereas styles are controlling mechanism and define the internal preferences and value system.

Among the different cognitive/ learning styles, we are enumerating some of the more important in the following.

Hill's Cognitive Style Mapping

Hill has built a cognitive style coefficient as a function of symbols and meanings (i.e., the preferred form in which an individual encodes information), cultural determinants (i.e., family, colleagues, etc.), modalities of inference (reasoning style, i.e., inductive, deductive, etc.) and a memory function.

It is interesting here to note that the cultural determinants, in the form of the influence of the country and cultural background on ones information processing style (learning style) have only recently been proposed for studying in the adaptive hypermedia community.

Kolb's Learning Styles

Kolb (1984) defined a 2-dimensional scale to represent learning styles, which leads to 4 extreme cases:

- *converger* (abstract, active): abstract conceptualization and active experimentation; great advantage in traditional IQ tests, decision making, problem solving, practical applications of theories; knowledge organizing: hypothetical-deductive; question: "How?".
- *diverger* (concrete, reflective): concrete experience and reflective observation; great advantage in imaginative abilities, awareness of meanings and values, generating alternative hypotheses and ideas; question: "Why?"
- *assimilator* (abstract, reflective): abstract conceptualization and reflective observation; great advantage in inductive reasoning, creating theoretical models; focus more on logical soundness and preciseness of ideas; question: "What?".
- *accomodator* (concrete, active): concrete experience and active experimentation; focus on risk taking, opportunity seeking, action; solve problems in trial-and-error manner; question: "What if?".

Dunn and Dunn's Learning Styles

Rita and Kenneth Dunn developed in 1974 a comprehensive learning style model on four axes:

- *environmental factors* (sound/noise level, light level, temperature, design setting)
- *emotional factors* (motivation, persistence, responsibility, structure)
- *sociological factors* (self-orientation, colleague orientation, authority orientation, pair orientation, team orientation)
- *physical factors* (perception, intake, time, mobility)

Although this model deals very little with the cognitive factor, this model is currently used in schools for pupils of grades 3-12 and a version has been developed for adults.

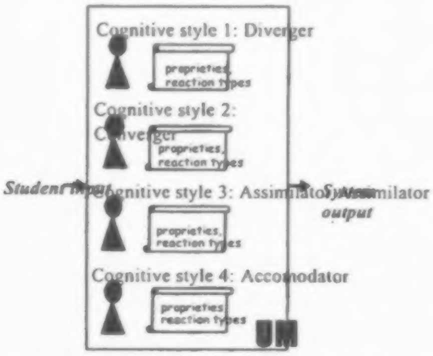
Herman Brain Dominance Model

Ned Herman classified in 1976 thinking styles into:

- *Quadrant A* (left brain, cerebral):
  analytical, logical, factual, critical and quantitative
- *Quadrant B* (left brain, limbic):
  sequential, structured, organized, planned, conservative and detailed
- *Quadrant C* (right brain, limbic):
  interpersonal, emotional, sensory, kinesthetic, symbolic and spiritual
- *Quadrant D* (right brain, cerebral):
  visual, holistic, innovative, conceptual, imaginative, artistic

His model classifies people according to their preferences (fig. 1), determining a dominant style (without excluding different preferences degrees for the remaining quadrants). Herman's model has some similarities to the Kolb model – such as the Converger could map approximately over the Quadrant A – but there is no complete one-to-one mapping.

Figure 1 shows an intuitive example of simple adaptability in a WWW distance learning model for classifying students into different cognitive styles (Cristea & Okamoto 2001a).



Cognitive style 1: Diverger
proprieties, reaction types
Cognitive style 2: Converger
proprieties, reaction types
Student input
Cognitive style 3: Assimilator
Assimilator
System output
proprieties, reaction types
Cognitive style 4: Accomodator
proprieties, reaction types
UM

Figure 1: I-O UM white-box of an educational system w. student separation by learning styles based on

Other Models

There are many other models, but among all those we would like to mention also the famous classification into:

1. *field dependent*
2. *field independent*

BEST COPY AVAILABLE

Field independence means the extent to which a person can perceive analytically and can distinguish the study object from the surroundings. Field dependent people, on the other hand, are dependent on external cues, and can, for instance, learn better if they have graphical support.

User Modeling

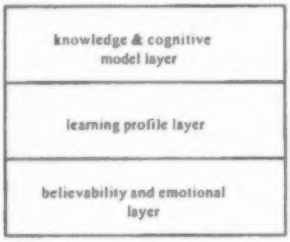
However, although very important in learning, the learning style is not the only prerequisite to be modeled for adaptivity and adaptability in WWW learning.

UM Layers

UM implies more layers, as depicted in figure 2 (Abou-Jaoude & Frasson 1999).

For instance, environmental factors (such as time, location, computing environment, network, physical handicaps, etc.) and the browsing behavior of a user should also be taken into account when generating and updating the information presentation and navigation structure of a hypermedia application.

A different perspective on studying the premises of user-modeling, and thus, the premises of adaptation and adaptability, is given by the MAO model (motivation – ability – opportunity: Hoyer & MacInns 2001), not presented here.



knowledge & cognitive model layer
learning profile layer
believability and emotional layer

Figure 2: Layers in student modeling

Considerations on UM

Building any model starts with the following:

- *feature definition,*
- *selection* and
- *extraction.*

As well known, this involves an iterative refinement process for achieving an efficiently working model, able to make predictions that meet reality, at least, statistically.

There exists no purely empirical approach to modeling. Even the definition of attributes/features and the selection of the relevant ones in a given context are actually theory driven, explicitly or not.

A prototype model of the learner can be used as a starting point that actually encodes some available general theoretical knowledge in the field of learning. Because of the large variability in human personality and in human behavior, and because the traits that are essential in various contexts are not the same, such a prototype model cannot be used directly in practice, without the penalty of being perceived as being rigid and biased. The model has to be customized by using empirical data – sets of examples collected for the given user, while interacting with the system.

If the features used to parameterize the initial model do not allow capturing specific detailed behavior, i.e., if the simple tuning of parameters cannot adapt the model to properly depict the user's profile, new features have to be extracted from the empirical data and added to the model.

The available collection of examples is never large enough to cover all possible classes in an unbiased manner, to avoid spurious correlation when elaborating a model. Small sets of exceptions may be poorly represented, or even ignored.

The combined use of theoretical knowledge and experimental results can offer the sought for solution, by allowing for incomplete and/or incorrect theoretic knowledge and for incomplete or noisy data. Such a system has the inherent capability to recover from errors. This is the reason why very new hybrid approaches emerged, based on AI (artificial intelligence) techniques, in particular NN (neural network) techniques.

Future Research Directions

The project's main outcome is to significantly contribute not only towards standardization of the new generation of ODL adaptation techniques and tools, but also to provide alternate styles of teaching and learning, optimally suited for ODL or a combination of ODL and traditional classroom teaching.

In particular, the project's output and products will follow the objectives and include:

- a set of relevant good practices of (UM based) adaptation techniques for education, based on current technology;
- as a byproduct of the above, it will generate counter-examples of sets of bad practices (or techniques) of (UM based) adaptation techniques for education, for a clear distinction from the above;
- a minimal set of relevant, necessary features for adaptation techniques in education. Generate typical features for distributed (Internet) environments, multimedia environments.
- a supplementary set of relevant (but not essential) features for adaptation techniques in education, as well as a few counter-examples of irrelevant features detected.
- Reports of the above, both internal (mid-stage), for partner's information and usage, and external, at conferences, workshops, etc. (e.g., AH, WebNet, ITS, UM, ED-MEDIA, CEC, etc.); final report will also be sent to standard bodies (IEEE, LTTF)
- a sample authoring system for adaptive techniques in education generated above;
- separately, one (or more) training system(s) based on the minimal set of relevant adaptive features, with possible addition of supplementary features
- evaluation, dissemination and promotion of results, especially focusing on the spread of understanding the innovative impact of the new issue of adaptivity and adaptability in the ODL, for classroom-based learning, distance learning modes or a combination of both and on the transferability to other domains.

Conclusion

This paper succinctly presents an emerging collaboration project of European dimension, with possible international significance. We clearly explain the necessity, at this stage, of a centralization of the accumulated knowledge on adaptivity and adaptability for WWW, especially in the domain of ODL (but also beyond). Moreover, we show that a unified standardization of adaptation techniques and technologies would benefit at first the European community, as this is a European project, but also the International WWW community, by establishing a common ground (vocabulary, ontology, methods, techniques, methodologies) towards more evolved UM techniques, and ultimately, increased user satisfaction. We start with a small group of experts in the field, but gladly invite specialists all over the world to join us in our effort towards improving and enhancing the Web and fully using the WWW potential. More information about this emerging project, officially starting autumn 2002, can be found at our local Minerva site.

AHA! Version 2.0
More Adaptation Flexibility for Authors

Paul De Bra[*], Ad Aerts, David Smits, Natalia Stash
Department of Computing Science
Eindhoven University of Technology (TUE)
PO Box 513, Eindhoven, The Netherlands
debra@win.tue.nl

Abstract: AHA! is a simple Web-based adaptive hypermedia system. Because of this simplicity it has been studied and experimented with in several research groups, see e.g. (Cini & Valdeni de Lima, 2002), (Calvi & Cristea, 2002), (Romero et al., 2002). This paper identifies shortcomings in AHA! and presents AHA! version 2.0 which tries to overcome the known problems with AHA! while maintaining its biggest asset: simplicity. We illustrate how different user modeling and adaptation aspects can be expressed in the new AHA! system (that would be difficult in the old system, and impossible in most other systems).

Introduction and Background

The development of the AHA! system started in 1996, when we created server-side software (CGI-scripts at that time) to add adaptation to an on-line course text on the subject of hypermedia. (For an introduction in the field of adaptive hypermedia, see (Brusilovsky, 2001). The AHA! software has been changed and extended somewhat over the years, resulting in what we will refer to as AHA! Version 1.0 in this paper, and which is described e.g. in (De Bra et al., 2000) and (De Bra & Ruiter, 2001). AHA! 1.0 is based on a simple architecture for an adaptive Web-based system:

- An application consists of a number of *concepts*. Some concepts represent Web-pages while others represent higher-level or abstract entities.
- The user model (for each user) consists of a *value* for each *concept*. The most common interpretation of this value is that the value means the *knowledge level* of the user with respect to the concept.
- Each time a user visits a page the *value* corresponding to that page is *increased*. In AHA! the author can define propagation rules that cause this increase to influence the value for other concepts. It is thus easy to define a structure of pages, sections and chapters, meaning that reading a page contributes to the knowledge of a section, and a knowledge increase for a section implies a (smaller) knowledge increase in the chapter. The propagated changes are arbitrary. It is also possible to register a *decrease* in knowledge of a concept by accessing a certain page.
- The author can define *requirements* for fragments of a page and for whole pages. Requirements are Boolean expressions over knowledge values for concepts. When the requirement for a fragment of the page to be presented is *true* the fragment is included in the presentation. (Otherwise the fragment is left out.) When the requirement for a page is *true* all anchors of links to this page are shown in a clearly visible color (typically blue or purple in AHA!). Otherwise the anchors are shown in *black*, meaning that they will be hidden in the text which is also black. (The black links are also *not underlined* to make them effectively hidden.)

As several researchers have pointed out, including (Calvi & Cristea, 2002), a consequence of the simplicity of AHA! is that it is only easy to create simple, straightforward applications. In this sense AHA! is in essence not very different from other adaptive systems like Interbook (Brusilovsky et al, 1998) which make it easy to develop one type of application, namely on-line courses. In (De Bra et al., 2000) we showed that it *is* possible to develop different types of applications in AHA! or to base adaptation on other user or browsing aspects than just knowledge. However, the examples that were given also showed that this development is difficult, and it was very clear that the user modeling and adaptation features of AHA! had to be "abused" in order to realize these alternative applications.

288

In AHA! Version 2.0 we address this problem through a richer user model structure and a domain and adaptation model with more advanced *requirement* and *generate* rules. The new features are based on the AHAM reference model (De Bra et al., 1999), which is an extension of the well-known Dexter reference model for hypermedia (Halasz & Schwartz, 1994).

The Domain Model / Adaptation Model in AHA! Version 2.0

AHA! deviates from the AHAM referemce model (De Bra et al., 1999) by not separating the *domain model* from the *adaptation model*. In AHA! the author defines *concepts*, along with *requirements* that determine under which conditions the user is "ready" to access the concept, and *generate rules* that specify how the browsing behavior of the user translates into user model updates. The *generate rules* are *condition-action rules* as used in active database theory (Baralis & Widom, 2000). We illustrate the AHA! concept structure with a continuation of the beer and chocolate example of (De Bra & Ruiter, 2001). AHA! 2.0 supports storing the concept structure in XML files or in a mySQL database. We use the XML representation in this paper. (There are some minor deviations between the syntax in this paper and the actual AHA! 2.0 syntax, for readability and simplicity reasons.)

The above concept definition is linked to the page "de_koninck.xhtml". This page is considered "desirable" by the system if the requirement ‘`beer.interest > 50`" is fulfilled. For adaptation this means that links to the de_koninck page will have a blue or purple anchor only for users with a high interest in beer. (The link will be blue before the first visit to the page and purple afterwards.) Uninterested users will not easily see the links to a special

BEST COPY AVAILABLE

beer like "De Koninck" because the link anchors are hidden by making them black like normal text, and not underlined. When a user accesses the de_koninck page the attribute `access` *temporarily* becomes true. The attribute is a "system" attribute, meaning its value is changed by a system even, in this case the access of the page. The attribute is not persistent, meaning that its value returns to the default value after dealing with the access event. The event causes the three actions (or "generateListItem"s) associated with this attribute to be considered for execution. The first action increases the interest in beer, but only if this interest is not yet 100 or more. The second action decreases the interest in chocolate, but only if this interest is not yet known to be high (but high enough to not become negative after the decrease). The third action registers that for interested users the knowledge about de_koninck becomes 100 and for uninterested users (who happen to find the page even though the links to it are hidden) the knowledge becomes only 35. "`knowledge`" is a persistent attribute of de_koninck, meaning that it is stored in the user model. Initially the attribute has the value 0 (the "default"). The rule associated with the knowledge attribute means that any change to this knowledge affects the knowledge of the higher level concept "`beer`" as well. 20% of the *change in the knowledge* of de_koninck is transferred to "`beer`". The "_" is used to indicate that the *change* in the attribute value is used, not the *value* of the attribute itself. As one can see from the example, *accessing* the de_koninck page changes the *interest* in beer and in chocolate and raises the *knowledge* of de_koninck; this knowledge change triggers the rule for the knowledge attribute of de_koninck, which will then raise the *knowledge* of beer. The change in interest for beer and chocolate and the change in knowledge of beer may also trigger rules associated with these concepts and attributes but that cannot be seen from the example as the concept structure of beer and chocolate is not given.

The above example may seem excessively verbose for expressing a few fairly simple rules for updating the user model. The given XML file only shows a single concept, whereas even a small application will already consist of 100 concepts or more. Fortunately a simple (Java applet based) authoring interface hides this verbose syntax from the author. Also, most applications require only a few simple types of rules, like having the access of a page raise knowledge, and like having knowledge propagate through a concept hierarchy.

Adaptive applications are sometimes concerned with different aspects of users, including *knowledge*, *interests*, *goals*, *learning style*, etc., and they may also wish to perform adaptation to other circumstances, like differences in browser, window size, network bandwidth, location, the user's background and Web experience, etc. The big advantage of AHA! 2.0 over its predecessor is that each aspect can be represented through different concepts or through different attributes of concepts. This makes it possible to clearly distinguish adaptation aspects that are unrelated to each other. The use of attributes also makes it possible to "combine" related adaptation aspects such as *knowledge about* a concept and *interest in* that same concept.

AHA! allows each concept to have a different set of attributes associated with it, and different condition-action rules. Attributes can be of type Boolean, integer or string. Each rule execution can trigger other rules, as seen in the example above. It is difficult to predict in general how the rule engine will behave as a whole. We have studied the problems of *termination* and *confluence* in the past (Wu et al., 2001). However, we believe the easiest way to enable authors to oversee the potential problems is to have an "`isPropagating`" attribute per action that indicates whether this action is allowed to trigger other actions or not. This was also proposed in the AHAM model (De Bra et al., 1999). As the action indicates (in the assignment) which attribute of which concept is updated, it is immediately clear which rule propagation will occur. As in all such rule systems (Baralis & Widom, 2000) there is a danger that the rule execution through this propagation mechanism will not terminate. In the previous version of AHA! an arbitrary propagation constraint was introduced (De Bra et al, 2000) that guaranteed termination. Unfortunately the constraint could also be a source of results the author did not anticipate. In AHA! 2.0 this constraint is lifted. Rules are always allowed to trigger each other, provided that the "`isPropagating`" attributes are set to true. Furthermore, the author can control more precisely the conditions under which a rule is allowed to be executed. In (Wu et al, 2001) we indicate how potential infinite loops can be detected during the authoring process.

In Figure 1 we show a two screendumps of the Java-based authoring tool for entering the concept structure, and the rules for updating the user model that is used for creating the adaptive presentation. The first image shows that the concept "`de_koninck`" has attributes "`access`" and "`knowledge`", and that three actions or generateListItems are associated with this attribute. The interface shows the condition (`<req>`) of each rule. The second image shows how the third generateListItem is defined. While entering expressions (like "`beer.interest > 50`") the tool shows the expression in red until it is syntactically correct and uses only concepts and attributes that have been previously defined. This guarantees that the complete structure of concepts, attributes and generateListItems is sound.

The User Model in AHA! Version 2.0

The most common type of user model in adaptive hypermedia applications (Brusilovsky, 2001) is the *overlay model*. For every concept and attribute in the domain model of the application a concept and attribute is kept in the user model. AHA! 2.0 follows the same philosophy, albeit with two exceptions:

- Attributes (of concepts) in the domain/adaptation model can be defined *not* to be *persistent*. The `access` attribute is a typical one. When the *adaptation engine* runs (when a page is accessed) these volatile attributes are initialized using the "default" value, and any updates to these values are lost when the engine terminates. The access attribute for instance is *false* for all concepts, but it will be temporarily true for the concept (page) that is accessed.
- When a user logs in for the first time a special "concept" is created, called `personal`, which is used to store user-related aspects that are not about the subject domain of the application. This information includes a name, email, login-id, password, and any other information the application asks for during the

BEST COPY AVAILABLE

login process. For our on-line course on hypermedia this information also includes the student's university and major. Because this information is represented through a concept it can be used for adaptation. We can thus present different assignments to students from different universities for instance. (In AHA! 1.0 the login information was not available for adaptation purposes.)

Below we show a small part of a user model for the imaginary beer application.

Document (Page) Formats

AHA! applications consist of sets of *pages* with *links* between them. Currently (in both version 1.0 and 2.0) the basic format is HTML, because that is what browsers understand. In AHA! 2.0 there are three "variants" in which source pages can be written (and which AHA! translates to plain HTML before sending it to the browser):

- There are some XML tags that have a special meaning for AHA!. The first AHA! format consists of XML pages with these tags, combined with HTML. The most important AHA! tags are the <if> tag for the conditional inclusion of fragments, and the <a> tag for links. The output of AHA! is the HTML source page in which some fragments may be deleted, and in which the links are shown in different colors depending on the "desirability" of the page that is the link destination.
- Plain HTML documents can also be used with AHA!. In such documents links are adapted like in the first format. While HTML documents do not take full advantage of the possibilities of AHA! it is important to allow them in order to include *external* documents in an adaptive application. (AHA! 2.0 can serve pages it first retrieves from other servers.)
- Using *modularized DTDs*, (and the Xerces XML parser that supports them) pages can now also be written in a format that combines AHA! tags with XHTML. The AHA! engine only looks at the AHA! tags to perform its adaptation. As a result it will be easy to extend AHA! with the capability to serve other

document formats combined with AHA! tags as well. (SMIL is one of the formats we wish to experiment with in the future.)

AHA! does not enforce or provide any special page formats. We are using AHA! in an on-line course without using HTML frames, and in another course with frames, and also with Javascript.

Examples of AHA! applications

The use of AHA! for modeling and adapting to *knowledge* and *interests* has been shown in previous sections. The versatility of AHA! becomes apparent when one looks at the following two small illustrations of completely different adaptation:

- In one on-line course we wished to have two presentations: a terse one (like viewgraphs) and a verbose one (like full course text). By letting the user set a *verbosity* level (which can be implemented as an attribute of the "personal" concept) we could have the system select fragments to show and hide. Currently we provide only two levels (terse of verbose) in that course, but by using an integer attribute we could also introduce more levels, showing more and more details and longer explanations as the verbosity level is cranked up.
- Our course that uses frames has a "navigation bar" in the left frame, and shows the pages in the (larger) right frame. The navigation bar shows course topics, and can optionally show a submenu for each topic. When a page on a certain topic is shown the corresponding menu should be opened and other menus should be closed. We realized this by turning all the menus into fragments to be conditionally included. Each time a page is accessed it activates the corresponding menu. The activation is done through a one line Javascript program that tells the browser to reload the navigation bar. There are two ways to implement the menu system in AHA!. One way is to create a "menu" concept with an Boolean attribute for each menu. Each page access triggers a set of rules that open up the appropriate menu(s) and close the others. It is possible in this scheme to leave more than one menu open. A drawback of this solution is that when a new topic is added to the course a large number of rules must be added to close the menu for that topic whenever any page from any other topic is accessed. A second way is to create an integer or string menu attribute (for either the personal concept or a menu concept). Each menu is assigned a number or name, and each page sets the menu attribute to the number or name of the menu to be opened. This solution does not have a problem when new topics are added. A drawback of this solution however is that only one menu can be open at once.

Adaptation features like these two could already be expressed in AHA! 1.0 but that required playing tricks with the concepts and adaptation rules. In AHA! 2.0 one can define concepts and attributes with a specific special purpose in mind and the associated rules cannot be easily "mixed up" with concepts and attributes that are used to represent knowledge and interest. We consider the ability to clearly distinguish different subparts of the domain/adaptation model, each having a different purpose, to be the biggest advantage of our new AHA! version.

Conclusions and Future Work

With AHA! 2.0 we have provided a versatile user modeling and adaptation tool. We hope that AHA! will be suitable for many different types of applications. Our experience with using AHA! for on-line courses has shown that in addition to modeling knowledge and providing adaptation based on it, AHA! can also be used to provide adaptation to personal aspects of a user, including preferences (like color or verbose vs. terse text).

The presentation format in AHA! is completely up to the author. The structure with concepts and attributes can also be used to help in creating the presentation. We for instance showed how to create a navigation frame with menu and submenus.

While we are still gaining experience in using AHA! 2.0 we already have a wish-list for a future version. Linking in AHA! is page-based. We plan to allow links to a higher level concept in the future, along with the automatic selection of the best page to be shown when a user "clicks" on such a link. We also plan to allow more flexible page construction. Currently a page consists of a sequence of fragments that are conditionally included, in a fixed order only. For information retrieval applications we need to allow at least the sorting of fragments.

Acknowledgement

The development of AHA! was made possible through a grant of the NLnet Foundation. Apart from them we would also like to thank the many researchers who have studied our previous research and development on AHA! and some of which have even developed applications with AHA!. Their research and experience reports have been very valuable in deciding how to extend and improve AHA! so that more people will become able to use it to develop adaptive courses and possibly also other adaptive applications.

Group and Task Experience: Implications for Computer-Mediated Groupwork in the Workplace

Christina Dehler
Department of Education
California State Polytechnic University, Pomona
United States
cmdehler@csupomona.edu

Abstract: Groupwork carried out via CMC are now a fact of life in the work place. This study investigates the effects of group membership and task experience on asynchronous computer-mediated groupwork. Groups acquiring task experience as groups during weeks 1 and 2 performed better on the final task at week 3 compared to groups in other treatment conditions. On measures of group process and group member reactions, participants acquiring group and task experience spent less time on the group task and expressed more satisfaction with, and confidence in, the final task solution. Implications for the workplace are that practice of computer mediated group tasks in stable groups is advisable. Training and work environments that expose work groups to computer-mediated tasks and provide opportunity and time to work on complex problems, would improve group performance. Subsequent training would focus on facilitating the transfer of skills and knowledge to new contexts.

Introduction

The prevalence of computer-mediated groupwork in organizations is such that group tasks carried out via CMC are now a "fact of life" in the work place. Two factors are identified in the literature as possible mediating factors in computer-mediated group performance, competencies and social experiences: Group membership stability and task experience. Groupwork research suggests that increased experience of a group as a group and increased experience of the group with a task both tend to improve the efficiency of the groupwork and overall quality of the work produced (Cannon-Bowers, Tannenbaum, Salas & Volpe, 1995; Hollingshead, 1998a and 1998b; Littlepage, Robison, Reddington, 1997; McIntyre & Salas, 1995; Wittembaum & Stassser, 1995). Such effects, however, have not yet been empirically studied in an asynchronous computer-mediated groupwork context nor systematically examined over a prolonged period of observation (McGrath, 1993). Therefore, this study investigates the effects of membership continuity and task experience on asynchronous computer-mediated groupwork. The group membership factor represents the two conditions under which groups may perform: Stable (unchanging) group membership and changing group membership. The task experience factor is determined by whether or not groups engage in task practice prior to the assessment of group performance.

Effects of group and task experience on computer-mediated groupwork

Group performance

Group members that acquire experience with each other and with a particular task benefit from the knowledge and skills gained, specific to both the task and the team (Cannon-Bowers, Tannenbaum, Salas, & Volpe 1995; Salas & Cannon-Bowers, 1997). As both individual- and group-level competencies develop, group processes are facilitated thereby resulting in better group performance. Recent research in the areas of team training (Cannon-Bowers, et al., 1995; Cannon-Bowers & Salas 1997; Cannon-Bowers, Salas, Blickensderfer & Bowers, 1998) and group practice (Hollingshead, 1998a; Hollingshead, 1998b; Salas & Cannon-Bowers, 1997; Littlepage et al., 1997; Moreland & Wingert, 1995) consistently shows that groups acquiring task-related experience as stable groups perform better than those whose members do not acquire this type of experience. The implication for the present research is that in order to effectively carry out a computer-mediated task requiring a high level of interdependence (i.e., a judgment task), groups acquiring task experience as stable groups will perform better. Taking the aforementioned into consideration, the following hypothesis regarding group performance is tested. *Hypothesis 1*: Groups acquiring judgment task experience as stable groups will perform better on the final judgment problem than groups in any other treatment condition.

Group process –time on task

Group process and interaction, consisting of communication and coordination skill dimensions, are required behaviours for effective task execution (Cannon-Bowers et al., 1995). Provided that the group membership, task type and groupwork context remain constant, the increase in experience that occurs over time allows the group to progressively re-adapt the group-task-context fit to take advantage of the increased predictability, reduced ambiguity and reduced coordination (Cannon-Bowers, et al. 1995; McGrath & Hollingshead, 1994; Hollingshead, McGrath & O'Connor, 1993; McGrath, Arrow, Gruenfeld, Hollingshead & O'Connor, 1993). As group norms of communication and task performance become established over time, group members require lesser amounts of time to complete the task effectively. Based on the aforementioned rationale, the following prediction is made. *Hypothesis 2*: Regarding time on task, individuals who did not acquire group or task-related experience will spend more time on the final judgment task.

Satisfaction with process

Recent research carried out by Benbunan-Fich and Hiltz (1999), Galegher and Kraut (1994), Straus and McGrath (1994), Warkentin, Sayeed and Hightower (1997), and Wilson, Morrison and Napier (1997), among others, affirms that groups carrying out collaborative work via CMC systems tend to be less satisfied with group process than their face-to-face counterparts. In short, results from comparative studies that don't extend beyond one data collection session suggest that computer-mediated groups must work harder to accomplish the same results as face-to-face groups (Galegher & Kraut, 1994). However, if group members given ample time to familiarize themselves and acquire experience with the communication technology, fellow group members, the task, and the groupwork context, previous findings about satisfaction may not entirely hold true. There is evidence that even minimal experience with group members and task work alters group process and performance (Burke & Chidambaram, 1999; Hollingshead, 1998a, 1998b; Littlepage et al., 1997; McGrath, Arrow, Gruenfeld, Hollingshead & O'Connor, 1993; Liang, Moreland & Argote, 1995; Moreland, Argote, & Krishnan, 1996). If these changes to group process and performance are of a facilitating nature, then it is reasonable to assume that member satisfaction regarding group process would also be positively affected by membership and task experience. Based on this reasoning, the following hypothesis about group member satisfaction with the computer-mediated group process is tested. *Hypothesis 3*: Regarding the final judgment task, individuals working in groups that acquired judgment task experience as stable groups will express higher levels of satisfaction with group process

Satisfaction with, and confidence in, group solution

If group members are satisfied with the computer-mediated group process of carrying out a group judgment task, it is reasonable to expect that group member satisfaction with the task solution will parallel this result. *Hypothesis 4*: With respect to the final judgment task, individuals working in groups that acquired judgment task experience as stable groups will express higher levels of satisfaction with the task solution.

Similarly, if group members are satisfied with the group task solution, it is reasonable to expect that confidence in the group solution will parallel this result. *Hypothesis 5*: Individuals acquiring judgment task experience as members of groups with stable membership will express higher levels of confidence that their group solution of the final judgment task is correct.

Method

Subjects and Groupwork Context

One hundred and sixty eight undergraduate students enrolled in Contemporary Business Thinking at Concordia University participated in this three-week study. Four treatment conditions were constructed using FirstClass whereby group membership and task experience conditions were created by varying participants' experiences during weeks 1 and 2, prior to the performance of the criterion judgment task at week 3. Groupwork took the form of asynchronous computer-mediated communication between group members in protected (group members only) conference areas. During weeks 1 and 2 of the study, subjects in the related task experience condition performed judgment tasks similar to week 3's task involving aesthetic or evaluative judgments for which there is no correct answer (McGrath, 1984; Wittenbaum & Stasser, 1996). Subjects in an unrelated task experience condition performed idea generation tasks during weeks 1 and 2. At week 3, all groups (i.e., all treatment conditions) performed the same judgment task (see Table 1 below).

Treatment conditions	Weeks		
	1	2	3
Stable membership with task experience	J_1	J_2	J_3
Stable membership without task experience	IG_1	IG_2	J_3
Changing membership with task experience	J_1	J_2	J_3
Changing membership without task experience	IG_1	IG_2	J_3

IG = Idea generation task
J = Judgment task

Table 1: Order of Task Assignment

Variables

Group membership consisted of two conditions—stable or changing. Similarly, task experience was operalitioned by two conditions—task experience and non-related task experience.

Group performance was measured by group solutions to the final judgment task, scored according to Straus' 1992 task scoring system of weighted values. Group process –time on task was measured with a single post-treatment item. Group members' social experiences were assessed with post-treatment questionnaire items inquiring about subjects' degree of satisfaction with the group process, group solution, as well as level of confidence in the group solution.

Experimental Procedure

Upon completion of a two-week FirstClass training and practice period, the three-week computer-mediated groupwork study began. Subjects were assigned randomly to conditions and to 3-person groups. Groups in the stable membership condition remained intact throughout the entire study (i.e., the same three people worked together). In contrast, groups in the changing membership condition were re-assigned to new 3-person groups at the start of every new week of the study such that no person worked with the same people more than once. At the start of Week 1, each subject was e-mailed his or her task with instructions on how to complete and submit it. Participants had two days to complete the task individually and submit a solution to the *Individual Submissions* conference area. Subjects then had the balance of the week to carry out the same task with their group. Upon completion of the group task, group solutions were submitted to a specified conference area, called *Group Submissions*, and each group member individually completed and submitted an online Week 1 Post-Task Questionnaire. During Weeks 2 and 3, subjects adhered to the same process described in Week 1 above, with subjects in the changing membership treatment condition being re-assigned to new 3-person groups. Upon submission of the final group solution at Week 3, subjects completed and submitted an online Post-Treatment Questionnaire and were given written debriefing of the study, via a personal e-mail message.

Results

A 2x2 between-subjects factorial design investigated the effects of group membership and task experience on group performance, group process and group members' social experiences. A total of 168 students participated in this research, forming a total of 56 three-person groups, 14 groups assigned to each treatment condition. The study was carried out over a period of three weeks with all four treatment groups (n=56) performing the same final judgment (criterion) task at week 3. Group performance was averaged across members in a group and assessed at the group level (n=56). All other dependent variables were based on data collected from the post-treatment questionnaire and were analyzed at the individual level (n=168). Analyses of all dependent measures were carried out via two-way analyses of variance (ANOVA) and a Pearson's correlation. In order to control for experimentwise type I error, the significance level for all F-tests was set at $p = .01$.

Group performance

Treatment mean scores for performance of the final judgment task (Task 3) reveal that groups acquiring judgment task experience as stable groups received higher task scores compared to groups in any of the other three treatment conditions (see Table 2).

Treatment	Mean	SD	N
Stable membership with task experience (SM/EXP)	7839.71	624.89	14
Stable membership without task experience (SM/NO EXP)	6721.36	1209.51	14
Changing membership with task experience (CM/EXP)	4823.57	1493.90	14
Changing membership without task experience (CM/NO EXP)	3230.00	1087.92	14
TOTAL	5653.66	2102.99	56

Table 2: Measures of central tendency for final task scores

A two-way ANOVA was carried out to confirm significant differences between these treatment means. As predicted, results show a main effect for membership ($M = 7280.53$, $M_{Changing} = 4026.78$), $F(1, 52) = 112.55$, $p < .01$ as well as a main effect for task experience ($M_{Experience} = 6331.64$, $M_{No\ Experience} = 4975.68$), $F(1,52) = 19.54$, $p < .01$. These results support Hypothesis 1.

Group process—time on task

Hypothesis 2 predicted that individuals who did not acquire group or task-related experience during weeks 1 and 2 would spend more time on the final judgment task. To test this hypothesis, subjects replied to the question "How much time did *you* spend on this assignment (in hours)?". A two-way ANOVA indicates a main effect for membership ($M = 2.66$, $M_{Changing} = 3.11$), $F(1,164) = 7.90$, $p < .01$, as well as a main effect for task experience ($M_{Experience} = 2.67$, $M_{No\ Experience} = 3.10$), $F(1,164) = 7.09$, $p < .01$. These results support Hypothesis 2.

Satisfaction with process

Post-treatment questionnaire item 22 "I felt pressured trying to complete the task in the allotted time" and item 23 "I felt our group needed more time to do a good job on this group task" were combined to yield a composite score of subjects' satisfaction with the process of carrying out the final judgment task. The coefficient alpha for the composite, calculated at the group member level, was .84. A two-way ANOVA showed a main effect for membership, with subjects assigned to groups with changing membership reporting higher levels of pressure to complete the task within the allotted time ($M_{Changing} = 4.13$, $M = 3.64$), $F(1,164) = 12.10$, $p < .01$. Unexpectedly, there was no main effect for task experience ($M_{Experience} = 3.77$, $M_{No\ Experience} = 4.00$), $F(1,164) = 2.60$, $p > .01$. Hypothesis 3 is partially supported.

Satisfaction with, and confidence in, group solution

Satisfaction with the group solution for the final judgment task was assessed with responses to item 21 of the post-treatment questionnaire "I am satisfied with the solutions my group came up with". Results of a two-way ANOVA showed a main effect for membership ($M = 3.90$, $M_{Changing} = 3.51$), $F(1,164) = 13.49$, $p < .01$ and a main effect for task experience ($M_{Experience} = 3.99$, $M_{No\ Experience} = 3.43$), $F(1,164) = 27.37$, $p < .01$. This results support Hypothesis 4.

Participants acquiring judgment task experience as members of groups with stable membership expressed higher levels of confidence in their group solution of the final task than individuals in any of the other three treatment conditions. An ANOVA on subjects' responses to item 19 "I am confident that the solutions our group came up with are correct" confirmed a main effect for membership ($M = 3.74$, $M_{Changing} = 3.27$), $F(1,164) = 20.10$, $p < .01$ and task experience ($M_{Experience} = 3.74$, $M_{No\ Experience} = 3.27$), $F(1,164) = 20.10$, $p < .01$. Hypothesis 5 is therefore supported.

Discussion and Implications for the Workplace

Results indicated that the more group members practice together as a group, the better they perform as a group on an asynchronous computer-mediated judgment task. The fact that groups acquiring judgment task experience in stable groups during weeks 1 and 2 scored substantially higher on the final task at week 3, compared to those who had not acquired these same types of experience, provides compelling evidence of the importance that gaining experience with a task as a stable group has on group performance.

Participants who became experienced with their group while carrying out judgment tasks reported spending less time on the final task. This suggests that subjects' accumulation of experience with computer-mediated judgment tasks as members of stable groups lead to a routinization of performance, thereby reducing of the amount of time required to carry out the final judgment task (McGrath, Arrow, Gurenfeld, Hollingshead & O'Connor, 1993). As group norms of communication and task execution became established over time, group members required lesser amounts of time to complete the final task effectively.

Reports of satisfaction with the process of carrying the task via asynchronous computer-mediated communication indicate that stable group membership positively affected subjects' level of satisfaction on this measure. Subjects assigned to groups with changing membership, regardless of whether or not they acquired judgment task experience, expressed lower levels of satisfaction with the process of completing the task. These participants, who, due to the lack of group familiarity, were not as adept at completing the judgment task, and generated the lowest group scores on the final task.

Group membership and task experience generated positive influences on subjects' levels of satisfaction with, and confidence in, the task solution. Significant correlations between these two measures and final task scores, $r = .79$, $p < .01$, provide further evidence that the computer-mediated group performance of tasks involving high levels of cooperation and conflict resolution is positively affected by group members' prior experience with the task and the group.

Computer-mediated groupwork in organizations is typically carried out among the same people, over a prolonged period of time and requires sustained interaction (Burke & Chidambaram, 1999). In this study, membership continuity positively affected group performance, time on task, and social reactions towards the group task. The implication for computer-mediated groupwork in organizations is that practice of tasks in stable groups would be an effective training method when the same group of people are going to be performing similar tasks in their jobs. Training and work environments that expose work groups to the general principles and procedures underlying computer-mediated tasks, that present them with a variety of relevant examples and give them the opportunity and time to work on several similar problems would likely lead to improved group performance.

To ensure that training does not compartmentalize people, skills and knowledge into specific task or group activities, this type of training should be used as a facilitative measure. Workers would first acquire job-relevant computer-mediated groupwork skills in stable groups so that much of the work required to carry out the assigned task is facilitated by group and task experience. Subsequent training would extend beyond the familiar groupwork context, incorporating new tasks and altering group membership so that knowledge and skills are further developed. The objective is to design training and job environments that facilitate the transfer of skills and knowledge to new contexts (e.g., new tasks, new people, new CMC systems) so that workers can easily adapt to a variety of computer-mediated groupwork situations.

Evaluation of a High-end Distance Delivery MBA Program

Dennis Dicks
Associate Professor of Educational Technology Faculty of Arts and Science
e-learning consultant John Molson School of Business
Concordia University Montreal

Abstract

The John Molson School of Business at Concordia University in Montreal has been addressing the need for new skills in aviation management for almost a decade through its International Aviation MBA, in partnership with IATA. the School set out in early 1999 to create a version of the program which could be largely delivered at a distance, anywhere in the world. This paper evaluates the technical and pedagogical decisions which formed the program, successfully launched in 2000, now graduating its first cohort and welcoming its third..
On the technical side, after evaluating a number of commercial templates and courseware purveyors, we chose to develop a custom-made approach with a local provider, *Hypermedia-Builder*. On the pedagogical side, drawing upon extensive experience in multimedia production, we have provided intensive support for faculty members, on both technical and pedagogical issues, as they develop and deliver their courses. Feedback from students and other data indicate that the these efforts enabled the program to achieve its academic goals Our experience suggests a need for innovative approaches to the problem of evaluating technology-supported instruction.

Context

For the past 10 years, the John Molson School of Business at Concordia University in collaboration with the International Air Transport Association (IATA) has offered an accredited MBA degree focussed specifically on aviation, responding to a growing demand for superior management skills in the industry. The International Aviation MBA (IAMBA) requires students, largely mid-level executives in airlines, airports, and civil aviation authorities, to be on campus for intensive study over a 13-month period. For students, the quality of the program must outweigh the substantial costs in tuition, accommodation in Montreal, and time away from their jobs. To overcome the latter 2 of these cost barriers, the School decided to create the Global version (GAMBA) of the IAMBA, as a primarily distance-delivered program. This paper documents the strategic and tactical decisions which led to an on-time, on-budget launch of this very rich multimedia programand evaluates the outcomes of these decisions.

Strategic and Tactical Decisions

Concordia has positioned itself as an urban university catering to the workplace in a number of senses: by offering programs that respond to market demand, classes outside normal working ours, flexible entry requirements, small classes and lots of contact with faculty. This is our niche, where we compete very well with older and more famous institutions; so abandoning it for large-scale off-campus delivery, via the web for example, would probably be a fatal mistake. Instead, we have experimented with teaching technologies within our niches, largely in support of on-campus courses. Since 1995, development of instructional technologies has been a key plank in the strategic plan of the John Molson School of Business. The plan took concrete shape not only in the development of the technical infrastructure, including a Centre for Instructional Technology, but also in the hiring of multimedia production staff, instructional designers to guide their work and that of faculty, and an educational technologist (Dicks) to lead the team (Dicks and Genova, 2000). Thereafter, major decisions like the ones reported below have crystallized from lengthy debate involving academic leaders, faculty, instructional designers and technical staff.

For our first major project, we decided to convert two well-established niche programs, the Executive MBA (EMBA) and IAMBA to Laptop U. format. As prestigious programs, operating outside normal constraints on hiring and tuition, we considered them the best vehicle for the School's flagship venture into teaching technologies.

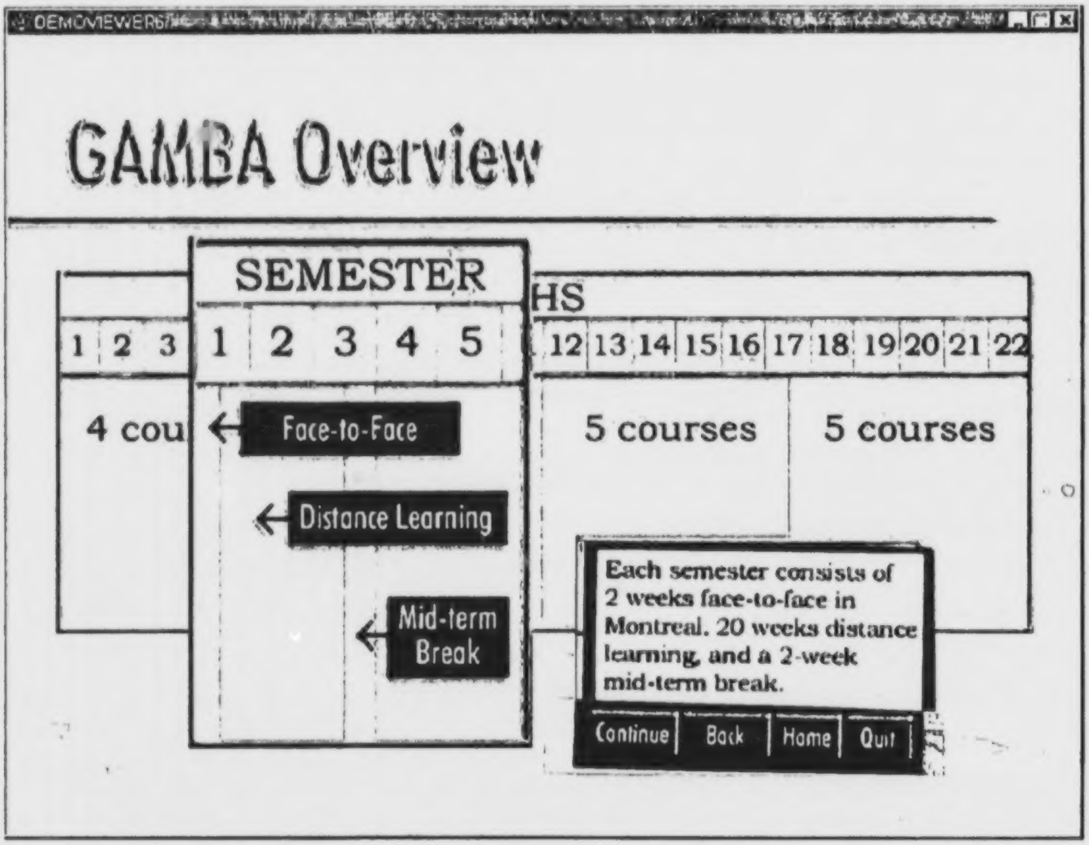
At the time, we imagined that laptop operation would simply mean converting to multi-media format the materials contained in each of the course binders which students received at the start of term. As it turned out the binders contained little more than what students typically receive at the start of any traditional class: an outline, some reprints, maybe some problems or cases. Not surprisingly, IAMBA/EMBA faculty were creating class

BEST COPY AVAILABLE

activities close in time to delivery, just as they do in other contexts. So at the outset the laptops, and the fully-wired intelligent classrooms we built for them, added little pedagogical value.

When we decided that we needed to reduce the accommodation and opportunity costs of the IAMBA by creating a distance version, we had to construct an entirely new strategy. Our target audience expected high-quality courseware commensurate with the substantial program tuition, and capable of sustaining their learning through a long period of remote study. We would have to put a lot of work into course materials so that as much as possible could be loaded onto student laptops before each term started. Our experience and analysis of the literature (e.g. Gibson, 1998) indicated that if we left students out on the end of the wire for excessive periods of time, they would become increasingly isolated and drop out. So we needed to balance the benefits of regular face-to-face contact with the costs of travel. Finally, if we planned to operate globally, ensuring students instant access to materials anywhere/anytime, we would want to reduce reliance upon potentially costly, slow, and unreliable telecommunications.

In view of these factors, we decided to distribute the program's 18 courses over 4 terms (Figure 1). Our plan called for students to visit the campus for two weeks of intensive classroom work, then return home to work on 20 weeks of material loaded onto their laptops.

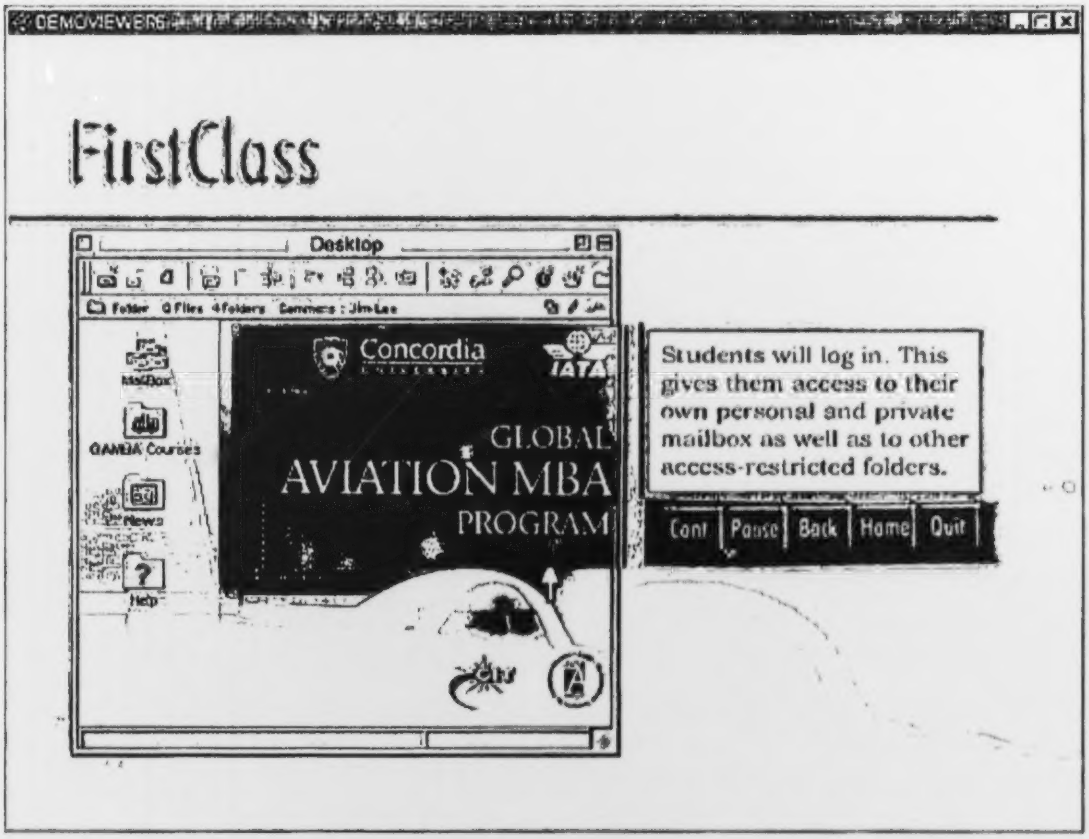


Each semester consists of 2 weeks face-to-face in Montreal. 20 weeks distance learning, and a 2-week mid-term break.

Figure 1. The Global version of the International Aviation MBA – 18 courses covered over 22 months, divided into 4 semesters. Superimposed is a typical semester which consists of 2 weeks on-campus followed by 20 weeks of study at a distance. This and subsequent figures are excerpts from our program demo on CD-ROM.

BEST COPY AVAILABLE

While off-campus, students would use our FirstClass groupware (Figure 2) to maintain contact, and to access or deliver assignments.



Students will log in. This gives them access to their own personal and private mailbox as well as to other access-restricted folders.

Figure 2. Desktop (in demo format) for the FirstClass groupware system, customized for the Global program. FirstClass is used for e-mail and chat communication, group work, assignments and instructor feedback.

To prepare, deliver and monitor courseware, we chose a hybrid technology which facilitates the creation of high-quality multimedia materials accessible on hard drive, CD-ROM or internet (Figure 3).

On the Pedagogical Side

In the run-up to our laptop projects, we conducted a number of pilot studies to experiment with different multimedia environments and development techniques. In this we were fortunate to have at Concordia one of the best Educational Technology programs in the world. Its Masters students are encouraged to complete their course projects and internships on real projects for real clients. Largely as a result of this practical experience, graduates go to work with prominent firms - Bombardier, the Canadian Space Agency, Soft Image, Nortel, Pfizer, Deloite Touche - as training developers, change managers, and so on. We engaged a half dozen of these students to develop prototypes for a distance course on Operations Research, and a web-based course on Personal Finance.

Figure 3. Hardware configuration for the Global program, using Hypermedia-Builder. The large circle on the right represents the course development and management component; the smaller one on the left represents the student laptop loaded with course materials but also in contact with the management component.

On the pedagogical side, these pilot studies taught us the value of providing a rich learning environment for students working at a distance; and we discovered the difficulties of getting faculty to generate the required material. Anyone familiar with corporate training program development knows that one of the most challenging tasks for the developer is creating a good working relationship with the subject matter expert (SME) so that information flows accurately and on time from expert to curriculum. Not surprisingly, this task can be just as difficult with that archetypical SME, the faculty member. In traditional university teaching, faculty work within a very flexible framework, adding, subtracting or modifying materials and methods on the fly. Like other SMEs, they are accustomed to developing and delivering their wisdom in familiar formats and time frames which typically do not match those imposed by an independent materials developer (Rickard, 1999). In contrast, multimedia production demands that instructional design be made explicit, that content be finalized long before delivery, in close collaboration with a multiskilled team (Dicks, 2000).

Our pilot projects and previous experience in industry convinced us to strengthen the SME-developer relationship by matching each faculty member with an experienced instructional designer. For this we hired, on contract at market rates, graduates of our MA Educational Technology program with a good mix of creative and social skills. Faculty, as part of their course contract, were paid a development stipend - an additional 40% of the regular on-campus fee. These teams began awkwardly, with faculty asking "what can the technology do?" and instructional designers starting from the opposite pole: "what do you want to teach?" But they quickly warmed to close, creative partnerships. As we grew more practiced, we also created a course-bidding process to locate faculty with the interest and ability to work in this challenging new environment.

On the Technical Side

BEST COPY AVAILABLE

On the technical side, having an established laptop program proved a great advantage: from the start we were able to define our students' off-campus computing environment. One of our key goals in the pilot projects was to create a seamless interface, so students would be able to participate in a variety of pedagogical activities without worrying about the underlying software. Our experiments uncovered some glitches in this respect with Web-CT, a platform favoured by the University's central information technology establishment.

Accordingly, we looked at a very sophisticated, expensive design and delivery tool called *Hypermedia-Builder* (Hyper-B; Figure 3), from Erigo Technologies Inc., Montreal. Hyper-B was developed by another of our Educational Technology graduates in response to technical and logistic problems he had encountered in designing multimedia teaching materials. Adopting a customized local product would entail much higher risks and costs, and lower compatibility compared with an off-the-shelf platform like Web-CT. However, our technical and pedagogical experts agreed that the risks were offset by Hyper-B's advantages. First it is designed for use by instructional designers, as its interface shows (Figure 4).

Instructional designers can learn its basic functions in a half-day, and input most material directly into a wide variety of formats. Second, the interface operates on a database, so that existing materials can be re-assembled, re-used, or revised with minimal effort. Third, the database is accessed by a Viewer (Figure 5) which functions much like a browser; materials can be recast as a new instructional package by simply changing the features of the Viewer. Fourth the database permits exceptional navigation and search features (Figure 5). Fifth, the upside of customization is that Hyper-B gives our program an exclusive panache, a more sophisticated image than available from standard course templates.

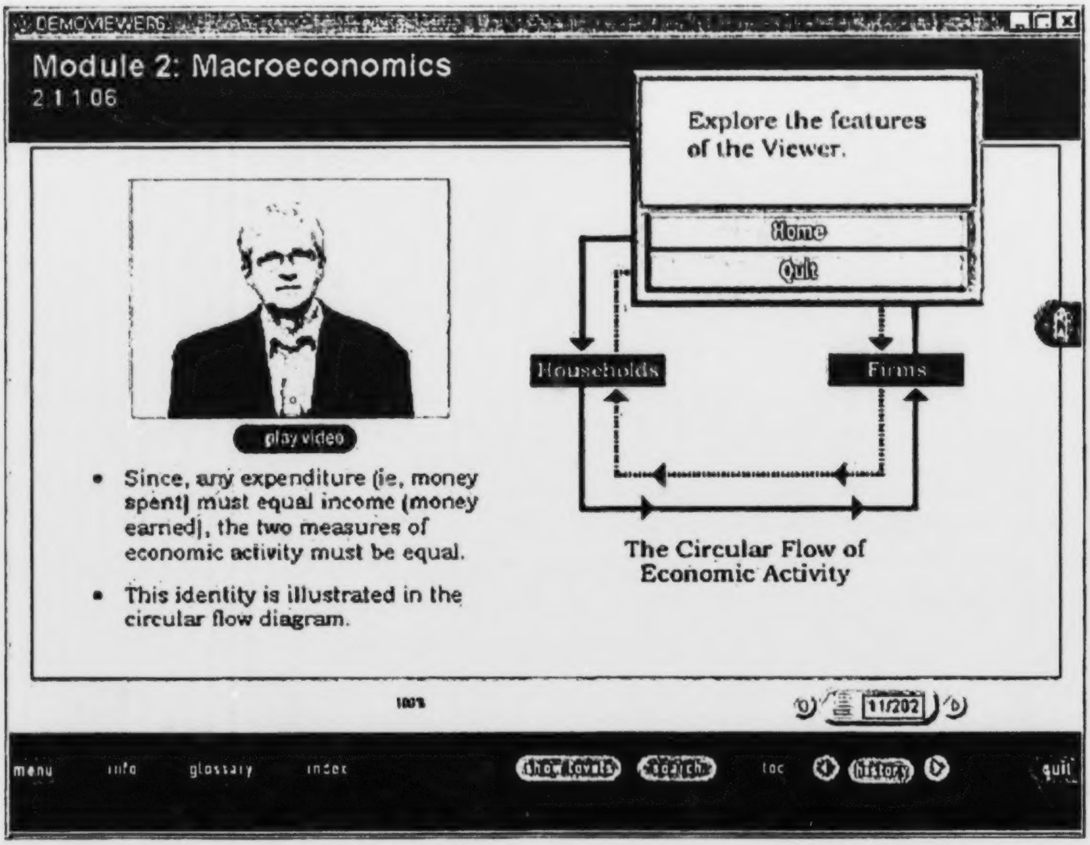
Last but hardly least, Hyper-B offers exceptional flexibility in configuring course delivery. Initially we leaned towards a web-based course along the lines offered by other platforms. This would potentially create line-cost and reliability problems if students lived outside North America, worked at home, or traveled; we expected a global program to encounter all these constraints. And so we opted for the configuration which loaded the course materials on the laptops, but still permitted remote updates of everything, and interactive course management as well (see Figure 3).

Faculty and instructional designers established their own modus operandi with an objective of completing the courseware to meet a strict deadline, so that alpha and beta testing could be conducted before delivery. Our schedules allowed them about 4 months from start to delivery for testing, and another month for revisions. After that, a semester's worth of courses would be loaded onto the laptop hard drives, together with any supportive software. The on-campus session for first term was extended to include distribution of the computers, plus hardware and software training. We designed the face-to-face session to establish an esprit de corps which, with regular communication via our FirstClass groupware, would help sustain students through the long distance-delivery session. Once they returned home, the students maintained weekly contact with their instructors for the next 20 weeks by means of FirstClass groupware. In addition, we hired one of our senior instructional designers to coordinate the flow of communications. We also used FirstClass to send and receive assignments and tests. Finally, to handle complex nomenclature, we provided each student with a hand-held scanner driven by the laptop with which they could submit handwritten exercises.



Module 2: Macroeconomics

Courseware Production

.On average, preparation of a single course required 50 days of an instructional designer's time and somewhat less faculty time. From the outset, courseware design varied considerably with the content and faculty teaching styles. Our first four courses, covering the basics (Accounting, Economics, Human Resources and Statistics) relied heavily on text and textbook; and we overestimated the volume of weekly exercises required to keep students moving. Subsequently, we lightened the assignment load, and started to vary courseware format as the whole team gained confidence and skill. Now, with 18 courses completed, our repertoire ranges from a simple wrap-around (text-based design supplementing a textbook), to wrap-around enriched with interactive activities, to videotaped lectures reinforced with interactive commentaries. The content of the courses varies widely over different disciplines, different types of knowledge, skills and activities. We have learned to adjust our pedagogical approaches to this variety by applying appropriate technological support (the Viewer, FirstClass, audio and videoconference) instead of trying to hammer everything into one template.

Evaluating our Experience

We started the program with a deliberately modest cohort of 15 students, 13 of them men. They came from 10 different countries, from Ecuador to New Zealand, and most were already working in the aviation sector. They are a remarkably diverse, talented and enthusiastic crowd; probably as a result, we have had no dropouts for academic reasons (two have interrupted studies due to the impact of September 11 events on the industry). This cohort is now graduating ; a second cohort has completed first year; and a third is just beginning.

From the outset we have conducted formative evaluations on the courseware, technology, and pedagogy, as well as summative evaluations of faculty performance. Feedback on courseware and pedagogy has been very helpful in making improvements for instructional design in general, and specifically for courses now being offered for the second and third time. As we anticipated, our students expected the program to provide much more than a one-way flow of information. Consequently, they reacted best to course designs which provided some choice in activities and pacing, interaction with the instructor, and what the course coordinator has called 'proactive counselling'- friendly inquiries about their progress and problems (McBryde, 2002). This reinforces a personal observation that the key feature of the program may be 'just-in-time' instruction. The real value of our sophisticated courseware development and delivery technology may well be that it provides in one place just what the student needs, just when needed.

Our technology performed extremely well, with the few initial glitches easily corrected through the internet with our built-in update function. In fact, after the first two terms we dropped technological issues from our evaluative questionnaire because the effort outweighed the information gained. During the first term, students, faculty and the course coordinator all rapidly learned to deal with different roles played by their laptops, the Viewer, FirstClass, the scanner. Both the Viewer and FirstClass proved to be remarkably user friendly. Ironically, hardware-specifically the laptop hard drive- has been the component most prone to failure (McBryde, 2002).

Conclusion

As a late entrants into distance education, we in the John Molson School of Business have drawn upon the experience of others to plan carefully. Our teaching technology strategy does not target the mass market, but rather a very specific niche. It does not depend upon the initiatives of individual faculty members to supply the range of skills required to program or even fill and modify templates, but rather requires close collaboration of dedicated team members with differentiated expertise. Its time lines are neither open nor flexible. Course preparation has to be completed long before term starts, even though revisions can in fact be made anytime thereafter. Faculty have to provide agreed materials on an agreed schedule, and sign off on completed materials by agreed dates. Our technology is not low-cost off the shelf but tailored to our needs at substantial expense which must be recovered in added value. Part of that added value lies in special features - a sophisticated image, impressive functionality. Part lies in more tangible benefits, like ease of revision, portability of materials to other applications, and the almost complete elimination of the programmer role, thus considerably reducing the risks of inaccurate or untimely communication in the production phase.

Have we succeeded? We can answer in several ways. First, we have no dropouts for academic reasons in the first cohort, in spite of a very mixed clientele. Esprit de corps is such that the first cohort has even asked that we add a final visit for graduation. Secondly, students, faculty and instructional design teams are generally pleased with the quality of the courseware and instruction. Thirdly, we have attracted a second and third cohort. Finally, if 'just-in-time' delivery is indeed a key feature in the program's success, we should be examin ing the role of opportunity cost- rather than amount or speed of learning for example - when we evaluate technology supported instruction.

For all the participants, this has been a very risky enterprise, in time, money and effort. Especially for faculty who have invested their time disproportionately to master new design skills which will affect the way they teach, whether they use technology or not.

ABSTRACT

In the face of panic and life-threatening situations in a hospital emergency room (ER), doctors must rely on well-defined procedures to assess the situation and respond appropriately. Since decisions to act must not only be timely, but also ingrained and swift, practice and experience in a wide range of situations is essential. This paper outlines the analysis, design and prototype development phases of a web-based role-play scenario in which the students of surgery can add to their repertoire of experience in ER medicine. Examples of existing online case study and role-play activities for clinical and ER training were studied. The instructional design decisions took into consideration the desirable attributes of these examples, but more importantly addressed their shortcomings. The prototype features an interface that enables the student to make many decisions at one time while proceeding to stabilise and diagnose the patient. After completing the procedure, the student's report is posted to an online discussion site for peer analysis and critique. The development of a future prototype is also discussed.

INTRODUCTION

In medicine, the use of information technology (IT) for teaching and learning began with the digital revolution of the early 1980s and the introduction of affordable personal computers for schools. The evolution of IT for the medical curriculum went from computer-based learning, such as the early low-graphics resolution tutorials, to computer controlled interactive videotape and videodisc, to immersive virtual reality simulations.

Today, the advent of the World Wide Web has added a new technology dimension: synchronous and asynchronous communication, and ubiquitous access. Slotte et al (2001) report that a 1999 survey showed that most medical school graduates in the USA "...used email (96%), medical information databases (92%) and the worldwide web (85%), especially for health care information". Unfortunately, as Turchin A. & Lehmann (2000) point out "...currently existing WWW-based medical educational applications seldom venture far beyond the boundaries of traditional curricula. Most of them serve as information depots, not offering significant qualitative improvement compared to a regular well-indexed textbook".

Concurrently, research and evaluation of technology in education has been examining the instructional design approaches for producing effective learning materials. Instructional design is a systematic approach to course development that ensures that specific learning goals are accomplished. Traditionally, instructional design models are based on behaviourist origins that stress the need for learning objectives, feedback and reinforcement to achieve a particular change in the learner. More progressive models of instructional design are now being fostered through a constructivist view of learning: the belief that individuals learn best from meaningful, self-directed and contextually relevant experiences. These models tend to use computer-mediated communication for peer-to-peer critique and collaborative learning activities, and have less emphasis on the teacher's role.

Bearman et al (2001) examined computer assisted instruction design approaches involving "virtual patients", where the student role-plays a doctor as he/she goes through scripted interactions with a "simulated" patient. The virtual patient design may range from the simple web-based to resource-intensive productions, but its instructional approach is either problem solving or narrative. The Interactive Patient (http://medicus.marshall.edu/medicus.htm) presenting a series of interactions over time with a coherent story line is an example of the narrative. While a repository of trauma cases (http://www.trauma.org) is an example of the problem solving approach.

Information and communication technology provides a new foundation for building what we now term as Internet enabled learning or e-learning. Looking for a feasible approach to provide a more meaningful online learning experience, the authors researched how an online role play simulation strategy, a variation of the problem solving approach in a virtual patient setting, could meet the needs of the surgical training program.

THE RATIONAL AND GOALS OF THE PROJECT

There are close to two hundred students in the fourth year of the medicine program, and ER medicine is part of their training. Students have a three-week posting to an emergency department of a teaching hospital where they receive basic cardiac life support training. They experience the management of trauma patients in the ER by observing and assisting the attending physicians. Concurrently the students take the American College of Surgeons Advanced Trauma Life Support course where in addition to attending lectures, they execute dry and wet simulationskills practice, and role-play on mock up (actors) patients.

BEST COPY AVAILABLE

Because of the number of students involved and the time allotted to role-play, each student gets very limited case simulation experience. Access to online role-play would enable each student to handle more scenarios, and even accrue some level of experience before their hospital posting. A more varied experience would translate to better management of real trauma cases during their posting.

The instructional design approach for this program reflects a pragmatic mix of strategies for teaching and learning. Our primary goal is to help the students self-assess their knowledge of related clinical procedures and laboratory tests needed to quickly stabilise and diagnose a trauma patient. While behavioural strategies are used to reinforce the basic airway, breathing and circulation (ABC) procedures critical to ER cases, constructivist learning strategies aim to encourage students to reflect on the processes involved and the experience gained. The constructivist strategies include framing the case study in a contextual experience and online discussion and debate to substantiate and compare their explanations with peers.

WHAT'S ON THE WEB NOW

An in-depth search of the World Wide Web yielded few sites dedicated to academic ER medicine. E-learning for ER medicine is not a common practice and the existing web sites have varying levels of sophistication in design. For most, the interface is limited to hyperlinked information, whether as additional data about a case or as feedback to multiple-choice questions (MCQs). None of the sites were designed to reinforce the ABC procedure for trauma cases. Some were no more than hypertext versions of print-based case studies.

Some simple case presentations can be found at Emergency Medicine Bulletin Board System (EMBBS) (http://www.embbs.com/ccc/ccc.html), including Clinical Reviews In-Depth and Academic Emergency Medicine's clinical pearls. Although they provide a convenience of access to information, these examples have no manner of learner interaction with the case. They are the equivalent to printed case studies. Others like the "CyberPatient Simulator" (http://www.mdchoice.com/cyberpt/cyber.asp) are slightly more sophisticated. Using basic web features, they present the case study as a series of decisions. As the learners proceed from one decision point to another, they get information about the case while responding to a sequence of questions. This design is linear with minimal interaction between the learner and the case. However, it still creates a presentation style where the learner can reflect on the information presented before viewing the consequences of any decision.

The Cases In Emergency Medicine web site of the University of Virginia School of Medicine (http://www.med.virginia.edu/med-ed/em/) makes use of more advanced web features. Dr. Stephen Huff has developed several web-based case simulations as scripted encounters with patients. Students progress through the case by selecting the appropriate sequence of investigation. Students get information about the case as they select to "Stabilise" the patient, get "History" and do a "Physical". Relevant questions about the case lead the student to selecting the appropriate "Action" to undertake.

This design is not only a more challenging experience to the learner, but it also features a set mode for presenting any case. Doctors can develop new cases by following the established sequence of presentation, making it easy to script and storyboard, and easy to program. But although this template is simple to use for content experts and programmers, it provides only basic user-interaction with the case simulation. A greater fidelity to real life experience, like enabling the student to indicate how procedures are accomplished, or make multiple decisions at one time is desirable.

THE DESIGN OF THE PROTOTYPE

Although many students in the Faculty of Medicine have Internet access from their homes, very few have subscription to wide band services such as ADSL or cable-modem. Therefore so called "video over the Internet" would have to be set-up for low bandwidth delivery. Since this configuration is woefully inadequate i.e. the size of the image is small and video image freezing is common due to network congestion, the prototype would not have video sequences. As well, because of the need for greater efficiency in developing future ER role-play simulation scenarios, the prototype would serve as a template for authoring subsequent cases. To produce new cases, content experts would only need to replace content (e.g. text and photos); the sequence and the structure of interaction remain the same.

In this prototype a mentor character, the chief of ER medicine, will set the stage for the trauma case and spell out his expectations for efficient handling of the case. The student will role-play the attending physician in ER under the watchful eye of the expert. As the strategy of role-play in this ER trauma case simulation is a student centred activity, the mentor's role is to provide feedback. Rather than observing or being prompted by the mentor, students need to practice applying their knowledge of ER procedures and diagnostic investigation.

The fundamental ABC sequence of attending to ER trauma is the first item to reinforce. Then, depending on the circumstance of the case, the attending physician (the student) must decide on which clinical and lab tests to perform at each stage of the ABC procedure. The student may also need to observe the patient or ask him some questions. These options are indicated in the program flowchart (Fig. 1). After being introduced to the case and selecting "Assess The Airway", the student can "Observe The Patient", "Talk To The Patient" or "Examine The Patient".

Fig. 2 Examine the Patient - Clinical Tests Flowchart

At this point the student must select all the appropriate clinical actions to perform. If some of the required actions have not been selected, the student will be asked to think it over, and complete the selection until all have been identified (see Fig. 2). If the student selects more than three clinical procedures that are not required, the simulation is terminated and the student is encouraged to study the ABC procedure before logging-on again. This aspect of the program will be examined during the prototype testing, and the number of errors allowed and the feedback messages presented will be addressed to reduce ambiguity and provide guidance for learning.

Having selected all the clinical tests to conduct, the student will then be asked to request the equipment needed to carry them out. The observations and results of clinical tests are posted in a "Clinical Notes" folder. Next the student is requested to select the appropriate laboratory tests or other investigation procedures. As in the clinical tests, in order to complete this section the student must select all the appropriate actions at this stage in the ABC procedure. Similarly, making too many inappropriate selections will terminate the simulation.

After selecting all of the appropriate lab tests and procedures such as x-rays and CT scans, the results are posted in the "Clinical Notes" folder, and the program hyperlinks to the next stage of the ABC procedure. The same interaction between the student and the program is repeated until the student has completed the "Assessing The Circulation" stage of the ABC procedure. Throughout, the Clinical Notes" folder is accessible by the student, and he/she can type comments at any time. It will therefore hold, in its sequential order, all the information gathered from observing and talking to the patient, and all the results of the procedures and

BEST COPY AVAILABLE

tests carried out. The student can use the information in this folder to support his/her diagnosis and recommendation for treatment.

The final element of this program will assign students to small online groups of 3 to 5 students. The diagnosis and recommendation for treatment that each student typed after completing the ABC procedure is automatically posted in a discussion forum type of environment, and students are asked to critique each other's findings. Since no names are shown on this site, weak or erroneous bogus reports can be inserted for the students to critique. After the students have agreed on the wording of a final report, it is emailed to the lecturer for a final review and feedback.

CONCLUSION

The development of the prototype for this case simulation role-play is underway. Formative evaluation is planned and will certainly modify, to some extent, the existing design. The goals, however, will not change. Students will experience learning in a relevant context and proceed through the ABC stages of trauma patient management. They will make decisions for stabilising and diagnosing patients in unique true-to-life cases and conclude by discussing, debating and substantiating their decisions. Students will learn to instinctively apply fundamental procedures that they will soon play out in real life.

The media selection for this prototype is based on circumventing the technology constraints of today's World Wide Web, but in the future ubiquitous access to streaming media will serve to complement and enhance the realism of the simulation. This, in fact, can be researched using our university wide-band Intranet and is expected to be featured in our next prototype design. More important is the need to examine the learning paradigm of online case simulation role-play and other student centred learning approaches. It is hoped that the implementation of a program based on this prototype will encourage research in the pedagogical implications and consequences of using this approach.

Evaluating assessment using n-dimensional filtering

Jon Dron (University of Brighton, UK), Chris Boyne (University of Brighton, UK), Richard Mitchell
(Inferdata, US)

Abstract

This paper describes the use of the CoFIND (Collaborative Filter in N Dimensions) system to evaluate two assessment styles. CoFIND is a resource database which organises itself around its users' needs. Learners enter resources, categorise, then rate them using "qualities," aspects of resources which learners find worthwhile, the n dimensions of CoFIND. Categories and qualities are created by CoFIND's users, so the system sculpts itself to a group's expressed needs.

We contrast two uses of CoFIND where students added and rated their own Web based assignments. The first of these provided useful material to help the students with further learning goals, while the second let them use skills they had acquired in a concrete setting. The use of qualities in each instance was very different, reflecting the students' different needs in each case.

Based on our results we suggest how virtual ecologies of self-organising groups of learners might be encouraged to thrive and grow.

Introduction

This paper describes an unusual approach to the evaluation of the effectiveness of assessed coursework provided for a group of graduate students at the University of Brighton, UK. It makes use of metadata exposed and created by the students to discover common values and attitudes to the work that they are required to perform. These metadata are the product of a Web-based system known as CoFIND (Collaborative Filter in N Dimensions).

About CoFIND

CoFIND has been described elsewhere and we present a relatively brief description of it here by way of foundation. The main focus of this paper is to examine the different kinds of metadata generated by the students and to draw some conclusions about how this relates to their perceptions of and attitude towards assessment tasks.

CoFIND is a self-organising resource database for learners. Resources (usually in the form of URLs, although the system can also take free text entries describing any object or which are themselves resources) are entered into the system by learners, who may have created the resource or have found it useful and wish to share it. Learners are encouraged to classify resources using existing classifications (following conventional usage we describe these as *topics*) or new ones which they enter themselves, collaboratively giving the system a functionality not dissimilar to that of a Web directory such as Yahoo or Newhoo.

One of CoFIND's unique features is its use of a form of metadata which we characterise as *qualities*. Qualities are those aspects of resources which learners consider important when choosing to use them. They are thus statements of value about a resource and might typically consist of words and phrases like *good for beginners*, *funny*, *comprehensive*, or *simple*. Qualities are used to give ratings to resources which provide potentially richer and subtler indications of the value of a resource than those of other collaborative rating systems or collaborative filtering engines such as NetPerceptions (www.netperceptions.com), DBLens (dblens.sourceforge.net), or MatchPoint (www.triplehop.com). Qualities are the n dimensions of CoFIND, providing a multi-faceted collaborative view of the system relevant to and generated by its users.

Through a combination of metrics based on the way that users interact with the system which include ratings, usage, and the frequency with the system is used, CoFIND arranges the presentation of topics, qualities and resources dynamically. It is designed to respond to individual local interactions such as rating a resource or selecting a quality to produce a self-organised system without a central designer.

CoFIND has been put to a range of different uses, including helping learners to find appropriate Web-based resources for their learning needs (Dron et al. 1999; Dron et al. 2000b; Dron et al. 2000a; Dron, Boyne & Mitchell 2001) and collaboratively discovering what makes a website good (Dron et al. 2000c). The studies discussed in this paper describe the use of CoFIND to enrich the process of student assessment, a side-effect of which is to allow us to find out some useful information about how students perceive the work that they are asked to perform.

A learning ecology

CoFIND's qualities are used to rate and discover resources which are not only appropriately classified as belonging to a particular topic but which fulfil specified needs described by the qualities. Resources classified as belonging to a particular topic are returned in a list ordered by their ratings for a selected quality. As ratings are given to resources, so their position in the list for that particular combination of topic and quality changes.

Learners may add new qualities if those which are already available do not seem appropriate to their needs. Unfortunately, a newly added quality will not have been used to rate any resources and so will be of little use in retrieving useful lists of resources. This could lead to a vicious circle, an example of the cold start phenomenon which affects most collaborative filtering systems (Harney 2000). The phenomenon occurs because the system only becomes useful once sufficient ratings have been given, but ratings are only given if the system is used, which is unlikely because there are insufficient ratings to make it useful. To help overcome this, when adding new qualities learners may allow them to inherit ratings from one which already exists. For example, a user adding the quality "simple" may allow it to inherit votes from "good for beginners." Like much of what underlies CoFIND, this borrows heavily from mechanisms which drive evolution in natural systems.

Qualities are presented as a list of hyperlinks, potentially in various different font sizes, dynamically ordered. Figure 1 shows one such list.

The size of each quality is proportional to the number of times the quality has been used to rate resources within the selected topic, compared with other qualities. Larger quality labels imply that more useful results will be found if the learner follows those links. The order of qualities in the list is partly determined by use (qualities which are most frequently selected), partly by votes cast using those qualities to rate resources within the selected topic, and partly by a weighting based mainly on the age of the quality. To cater for a potentially large number of qualities of low value to other learners, qualities may "die," dropping off the list entirely. This prevents inappropriate qualities from retaining a foothold in CoFIND's ecology. Qualities of little use get smaller, drop down the list and eventually disappear. Again, this process is inspired by natural evolutionary processes.

Stigmergy

The use of varying font sizes and dynamic ordering of the list returned is designed to make use of a positive feedback mechanism found widely in natural and human systems known as *stigmergy*, a kind of indirect communication via the environment (Heylighen 1999). Examples include the formation of ant trails, the construction of termite mounds or the emergence of forest footpaths. In stigmergic systems, each individual's actions affect its environment which in turn influences the actions of others. For example, ants returning to a nest with food leave a trail of pheremones. Ants which otherwise wander relatively aimlessly are more likely to follow a trail of pheremones. The stronger the trail, the greater the likelihood that others will follow it. As more ants return with food, the trail gets stronger. When the food eventually runs out, the scent dissipates and the trail vanishes. Within CoFIND, learners are more likely to select qualities in a larger font and/or higher up the list. Likewise, because learners are more likely to visit resources which are highly rated, they are more likely to provided ratings for resources which have already been rated, which (if the resources are considered worthwhile) means that the position of qualities on the list and their size is further enhanced.

Self-organisation

Without constraint, stigmergy could lead to what complexity theorists describe as a Stalinist regime (Kauffman 1995), a system locked into a fixed pattern of behaviour where novelty has no chance to take hold. We would equally wish to avoid what the same complexity theorists call a Red Queen Regime, where change is so frequent that no stability is ever reached and the system descends into chaos. CoFIND's algorithms are tuned to create a dynamic system balanced at the edge of chaos, with sufficient stability to create structure but with sufficient adaptability to cater for learners' changing needs. Driven by the positive forces of learners' needs and stigmergy, evolutionary forces act on the results, constraining growth through the survival of the fittest. This can result in a self-organised learning ecology of potentially high complexity and variegation, with different species of quality fitting different ecological niches which relate to the different and contextually situated needs of learners. Through their combined individual interactions, a clear structure to the available resources emerges without the intercession of a teacher or instructional designer.

The use of topics in the studies which this paper describes was intentionally constrained so we will not discuss the mechanism in detail here. In normal use topics are generated by students and are self-organised using a stigmergy and evolutionary processes to help to provide a guided path through a subject area. We have discussed this elsewhere (Dron et al. 2000a; Dron, Boyne & Mitchell 2001).

Through the use of qualities, CoFIND provides a unique glimpse of a group of learners' view of what is important in a learning resource. It becomes a mirror of the needs, aspirations and motivation of the learners who use it, whatever those needs may be. It is this aspect of the system which we make use of in the following studies.

Using CoFIND- two example case studies

Description of the case studies

Both of these studies involved the same group of 35 students studying for an intensive one-year conversion Masters degree in Information Systems. All of the students had previous degrees in subjects unrelated to Information Systems. The intensity of the course and its group-orientated ethos typically results in a very close-knit community of highly motivated individuals.

Both studies presented here relate to a stream of the course which teaches networking and Internet technologies, from low-end protocols through to Web application building. The networking and Internet technologies stream straddles two semesters. At the end of each semester is a traditional unseen examination preceded by a two-week personal assignment. These studies primarily look at the use of CoFIND as a support and evaluation mechanism for the work produced in these personal assignments.

The first assignment

The first assignment given at the end of the first semester required students to produce Web pages written using XHTML to provide tutorials on technologies related to the module. The students were allowed to choose any network-related topic which interested them, including but not limited to any topic taught on the stream. For some, this provided an opportunity to revise or clarify work already covered, which was therefore of interest to the entire cohort and would be perceived as useful preparation for the examination they were shortly to sit. For others, it was an opportunity to explore areas on which they were writing a 12,000 word dissertation due in the second semester. All students selected a topic related to one of these two functions. Given the intensive nature of the course this is to be expected, as the students needed to make the best use of the time available to achieve their main goal of gaining an MSc and did not wish to investigate a topic out of simple curiosity.

At the end of the assignment, the students were required to add references to their pages to CoFIND. They were also required to look at and rate at least three of their colleagues' tutorials, with a small penalty (a total of three percent of the marks) being applied to those who failed to do so. There was no need to implement this penalty, as all students rated more than three sites. Following discussions with the course leader it was decided that the students' own assessments of each other should not contribute to the formal mark received.

The students were already familiar with CoFIND as since the start of the stream it had acted as a resource base providing references which both they and the tutor had found and rated. It is significant that although the system had been used by all students leading to a database of nearly one hundred relevant rated resources, the level of activity and especially rating had not been very high, averaging around 10 ratings per week over the course of the semester.

The second assignment

The second assignment given at the end of the second semester required students to produce a Web-based application implementing some of the functionality of a system which they had already been analysing, designing and programming for other streams of the course, based on a rich case study designed to give a moderately authentic experience of working on an IT project. Crucially, the assignment was therefore perceived as an activity giving summary evidence of the skills which they had been learning during the latter half of the stream. The assignment was based on a fictitious company called *Stowaways* offering holidays on the rivers and canals of England.

Like the first assignment, students were required to enter links to their work into the CoFIND system with the threat of marks being deducted from students for failing to rate at least two of their colleagues' sites. Like the first assignment, there was no need to apply this penalty, although most students *only* rated two sites. Again, the course leader advised against allowing the students' own assessments to contribute to their formal mark for the module.

Results

Over three times as many ratings were given for the first assignment as for the second (288 for the first, 88 for the second). This did not seem to be unduly affected by other factors such as learning or boredom as, apart from during the period of the assignments and troughs during vacation periods, use of the system for sharing resources remained consistent throughout both semesters.

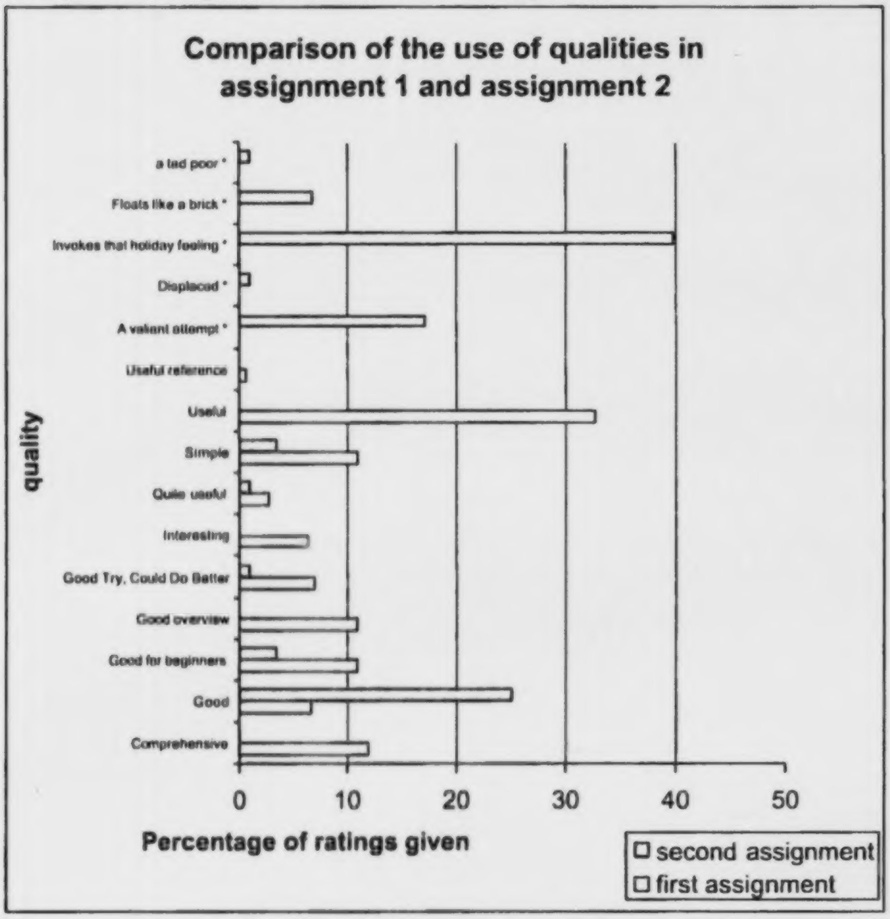

Figure 2 – comparison of use of qualities for the two assignments

As may be seen from figure 2, there is very little similarity between the use of qualities in the two assignments. Although new qualities were available and were added during the second assignment, all of the existing qualities used in the first assignment had survived the evolutionary process and were still available for the students to use. A closer look reveals that, in order of popularity, the top five qualities for the first assignment were *Useful, Comprehensive, Simple, Good for beginners, Good overview*. Three of these (including the top two) were not used at all for rating work supplied for the second assignment, and even those that were (*Good for beginners* and *Simple*) achieved less than five percent of the votes cast. By contrast, the top five qualities for the second (*Stowaways*) assignment were *Invokes that holiday feeling, Good, A valiant attempt, Floats like a brick*, *Good for beginners* and *Simple* (joint fifth place). Both assignments showed the traditional bell-curve in grades achieved, without any clear difference in the distribution of marks.

Discussion

Qualities as aids to learning

The qualities used by the students for the first assignment are broadly those that would be helpful in finding resources from which to learn and to revise for exams. They are the sort words which a teacher might use to describe resources from which a student might learn, whether explicitly or implicitly. If a teacher suggests that students read a particular resource it is by definition because he or she feels that the students would find it useful (the most popular quality for the first assignment). The teacher might then go on to explain why it is useful (for instance, it gives a comprehensive view of the subject, it is simple, good for beginners or it gives a good overview) which would help to match that resource to the needs of a particular student or group of students. One of the charms of the CoFIND system is that the students themselves are likely to have a better idea of how particular resources match their own needs than the teacher, at least when averaged, and the use of qualities in the first assignment seems to be a clear an expression of those needs.

By contrast, with the exception of the last two qualities in joint fifth place, there is nothing in the qualities for the second assignment which suggests any value at all as a learning resource. Instead, the qualities used are variants on the single dimension of good to not-good which is used in virtually all collaborative rating systems on the Web. In fact, interviews with students indicate that the last two qualities are not exceptions at all, but were supplied by the overly modest students who added the resources themselves, not as a description of their educational value but as a way of drawing attention to their inadequacy. Given that the second assignment was based around holidays on waterways the fact that two of the most popular qualities were humorous variations on the theme is noteworthy, again giving clear evidence that the students were not concerned with the outcome of their voting, merely that it was seen to be done.

Term ambiguity

Term ambiguity of the sort seen in the differing uses of *good for beginners* and *simple* is a difficult problem which affects any classification system (Lakoff 1987). It is primarily for this reason that CoFIND has been targeted squarely at small, tightly focussed cohorts of learners with clear and well defined needs, on the assumption that they would in general share a vocabulary and world view. As this study shows, even within such a constrained environment such world views are dynamic and transient things, shifting with the needs of the learners. Learning changes people and the qualities which they choose to assess learning resources provide a clear indication of this. How this affects the way that learners later perceive resources rated using an earlier world view has yet to be shown, but will make an interesting subject for further study.

Frequency of rating

The relevance to the students of the output of the two assignments is clearly demonstrated in the number of ratings given in each instance. The fact that the results of the second assignment were of no apparent further use resulted in the minimum of ratings being given, driven almost entirely by the extrinsic motivation of not wanting to lose any marks, but without the intrinsic motivation provided by the first assignment of wanting to help to build a collaborative resource of further use to the learning needs of the cohort.

Justifications for assessment are often given on the grounds that they help to provide focus and motivation for students, as well as providing a basis for much of the formative process essential to learning (Bruner 1966; Gagne 1985). They are also an interface between examining institutions and the outside world, giving an indication of a student's worth to potential future employers. However, at the same time they are often obstacles to learning, parts of a system which feeds on itself at the expense of the needs of its users, whose primary motivation we would wish to be to learn, rather than to achieve a qualification (Whitehead 1929; Illich 1971; Holt 1977). Our findings provide some evidence that, when used purely as an extrinsic motivator, assessments are far less significant to the students than when those assessments contribute directly to that learning process. This is entirely in keeping with the model of engaged learning proposed by Jones et al (1995) who state firmly that assessment should involve a performance or demonstration, usually for a real audience and useful purpose, as well as having meaning and purpose for the learner. In this case there is a second layer of indirection at work, inasmuch as from the students' perspective the most useful function served by the results of the assessed task in the first assessment was to feed the their needs in addressing a further assessment (the end-of-semester examination).

Possibilities

We can imagine a scenario where CoFIND might be used to collaboratively generate an entire course in higher education. The course could be constructed from a set of assessments, each building on the last, each leading to collaboratively generated further knowledge with direct relevance to the next task. More controversially, It is possible that such a system might be formed without the direct intercession of a teacher in the design process. If students were to be given sufficient resources (including static materials, reactive support from subject experts and suitable infrastructure for communication) and aimed very roughly in the right direction, the most highly rated student resources could provide the input for the next wave of assessment. A teacher or other arbiter (perhaps the students themselves) could take up the most popular themes, topics and areas and set them as the focus of another CoFIND-mediated investigation. The process would continue until the students felt that they had learned enough or an external arbiter (with full access to student work and opinions about it through CoFIND) considered that learning had been demonstrated. In this way a self-organised system of learning might be formed, with learning resources (being generated by the students themselves) naturally falling within Vygotsky's zones of proximal development (Vygotsky 1978). The approach would best be suited to a subject with a large body of knowledge mapped to a loose and flexible body of theory, as found in the medical and computing professions, where knowledge is achieved as a gestalt more than being assembled from sturdy foundations.

Conclusions

CoFIND is intended as a tool to aid collaborative learning, but it is clear from the example of these two small studies that in order for it to be effective it needs to be considered as part of a larger system. Simple application of technology is not enough to bring about useful collaboration, even where that technology is explicitly designed to replace some of the mediation role of traditional teaching.

CoFIND has shown itself to be a useful research tool which can form an image of the collective attitude of a group of students towards a body of work. In the studies we have looked at, CoFIND has helped to bring the attitudes of a group towards assessment tasks into sharp relief, demonstrating something we should have known already, that authentic tasks designed which have applicability to student needs are more likely to be useful to them than those which do not. Viewed from students' own perspectives, such needs may be quite different from those which we as teachers believe them to be. The second case study presented here was a well-intentioned and carefully designed integrated assignment providing what the teaching staff saw as an authentic grounding in the subject of study. However, the system of assessment and examination controls and determines the students' priorities and goals far more than the promise of some distant set of learning objectives (Dewey 1897). The success of the first assignment lies not in the success of the students in achieving the desired learning objectives but in its relevance to their immediate needs, consequently providing greater long term value than that of the second. With students benefiting from each other's work, gaining the benefits of "teachback" (Pask 1976) through explaining a subject to others all within a framework which reflects their own conceptions of what is of value in a learning resource, it is possible to conceive of systems incorporating tools like CoFIND, where the role of the teacher may dissolve further into the background as an instigator, a helper and a validator rather than a provider of knowledge.

A Framework for Evaluation & Selection of E-Learning Solutions

Deniz Eseryel
Instructional Design, Development, & Evaluation
Syracuse University
United States
deseryel@syr.edu

Abstract: This paper presents a comprehensive evaluation framework for a variety of organizations that wish to find the perfect fit between the needs of the organization and the online solutions they adopt. The framework described in this article is an outcome of a collaborative effort between the department of Instructional Design, Development, and Evaluation (IDD&E) of Syracuse University and one of the leading companies in North East that provides training and development for large and mid-size corporations.

Introduction

In the last years of the twentieth century, the world of education has changed. Use of the Internet has grown dramatically in training and education. Internet and related technologies have changed the way we communicate and have provided unprecedented access to information. It has also changed our expectations of education – how, when, where, and in what form we expect to access opportunities for learning. As a result, educational institutions are now faced with tough decisions about which learning technologies to adopt. Not only educational organizations but also business and industry are struggling to select the online training solution that fit their organizational and technical requirements.

On the other hand, when speaking of online learning environments, one often begins to feel lost. Vendors of e-learning related products employ a variety of terms to describe their products. Moreover, different vendors do not necessarily mean the same thing when they use the same terms. Many terms are used interchangeably, and sometimes one term is used to mean different things. With so many terms, it is difficult to distinguish the different types of learning environments. An organization wishing to select an environment that is appropriate to its needs often finds itself in the situation of comparing apples and oranges, as the products and features being compared really have little in common. In an attempt to ease the process and to provide some basis for comparison, a number of different evaluation frameworks have been proposed. However, existing frameworks either do not provide tools for a spectrum of different online learning environments or they have simply stayed behind of the new developments in the field.

The aim of this paper is to present a more comprehensive evaluation framework for a variety of organizations that wish to find the perfect fit between the needs of the organization and the online solutions they adopt. The framework described in this article was developed as a result of a collaboration project between the department of Instructional Design, Development, and Evaluation (IDD&E) of Syracuse University and one of the leading companies in North East that provides training and development for large and mid-size corporations.

The following section provides a brief overview of the eLearning project. Then the different dimensions of the proposed evaluation framework are discussed. The paper concludes with the description of the utilization of evaluation framework followed by discussions on future directions.

The eLearning Project

The eLearning project is an outcome of an initial understanding between a leading provider of training and development for large and mid-size corporations and the department of IDD&E at Syracuse

University. As a response to demands from business and industry, this company felt the need to extend its services by consulting in the area of online training. The resulting project, i.e., the eLearning project, called for a collaborative engagement between a higher education institution and the industry. The task as set out was to identify and evaluate existing online learning products so that the company would be able to recommend the best blend of online learning solutions to its customers.

The initial project proposal was for seven months starting in June 2001. The effort was broken into six cyclical phases:

1. Project management
2. Identification of existing e-learning products
3. Initial review of e-learning products
4. Categorization
5. Evaluation
6. Reporting and dissemination

Internet is heavily utilized during the second and third phases, where we identified an overwhelming amount of e-learning related products and a number of Web sites that provide information about them. As each product was identified, the project members reviewed the demo version of the product as well as the information at the product's Web site and at the other Web sites. This initial review phase resulted with a report including the following information for each product identified:

- Product name
- Vendor information
- URL
- History
- Trends Info
- Learning approach
- Functionality
- Standards
- Experiences with demo version

During the initial review, it became obvious that there was a need for a comprehensive evaluation framework that could take into account the diversity and richness of e-learning related products. Such a framework needed to be constructed so that it allowed comparison of similar products for the purposes of selecting the best possible solution given organization's online training needs. Many Web sites offer information about the features available in different e-learning products; however, any sort of categorization is usually lacking. Using such Web sites for the purposes of selecting an online learning solution means comparing the features of a series of random systems. We, on the other hand, were trying to develop a system that helps the organizations select the best blend of online learning solutions that meets their organizational and technical requirements. Therefore, the first dimension of the proposed evaluation framework deals with categorization of e-learning related products. This is discussed in the following section.

Categorization of E-Learning Related Products

From the initial review of existing e-learning products, two things were most evident. First of all, many terms were used interchangeably, and sometimes, one term was used to mean different things. With so many terms, it was difficult to identify the different types of e-learning products. This terminology problem showed itself in the discourse of researchers and practitioners in the field. Therefore, in identifying different product categories, our first challenge was to examine different uses and definitions of the terminology in the field.

The second problem also concerned the use of terminology. This one, however, was related to how vendors viewed and marketed their products. In an attempt to distinguish themselves from each other, vendors used rather fancy terminology while describing their products. For instance, a product marketed as a total online learning solution was not providing a total solution at all. Broadbent (2001) argues the similar point when she notes the different terms that vendors of Learning Management Systems (LMS) use to market their products. Some examples of these terms include learning portal, best-of-breed technology, an end-to-end solution, an e-learning solution, a truly blended e-learning solution, an integrated learning and management system, a breakthrough Learning Management System, revolutionary elearning tools, one powerful solution, a complete turnkey private distance learning solution, a global learning management solution, a learning solution, e-learning infrastructure technology, open learning environment, and of course, the total solution (Broadbent, 2001).

E-learning products display a great deal of diversity with respect to their capabilities and features. Any organization wishing to select an e-learning solution that is appropriate to its needs would find itself in the situation of comparing apples and oranges. It is significantly more profitable to compare similar products from a specific category of products that may meet organization's needs than to compare the features of a series of random products. Therefore, it was important for us to distinguish the different types of e-learning related products in order to provide some basis for evaluation and comparison. Therefore, the first dimension of the proposed evaluation framework concerns the categorization of elearning related products.

There are a number of categorization schemes proposed in the literature. A review of existing categorization schemes suggest that there is a need to develop a new categorization scheme. The reason is three-folds. First of all, due to rapid consolidations in the elearning product market any categorization schemes that are more than two years old face the danger of being outdated. Especially, in the last few years, many product categories have disappeared due to consolidation or market forces. On the other hand, existing products' capabilities and features have greatly been expanded, therefore, necessitating new product categories.

Secondly, some of the existing categorization schemes are not useful for the purposes of comparison and selection. For instance, a categorization scheme based on the origin of the system may be an interesting study but it does not aid decision-making of organizations.

The third problem we observed with existing categorization schemes is that some of them do not suggest mutually exclusive categories. In such a categorization scheme, it is possible to place the same product in more than one category. As a result, CuseeMe, which is an online conferencing tool with no other features may sit beside Authorware, which is a multimedia authoring tool, and WebCT, which is an online course creation and delivery system. This is definitely not a desirable situation for the purposes of comparison.

Nevertheless, some of the existing categorization schemes were useful for they offer organizational and technical criteria that remain valid in the selection process. Also, existing categorization schemes helped us identify the terminology researchers use. After a careful analysis of the capabilities of nearly one hundred e-learning products, following categories are proposed:

1. Synchronous Learning Systems
2. Course Management Systems
3. Learning Management Systems
4. Total Solutions
5. Delivery Support Tools
6. Development Support Tools
7. WWW Publishing Tools
8. Media Creation Tools

Synchronous Learning Systems (SLS) are those that provide environments where learners and instructors interact in real time, often at a scheduled event, usually through audio- or video-conferencing. Some of these systems may also provide limited asynchronous capabilities as well as student management and progress tracking tools. An example of a synchronous system would be Centra Symposium.

The category of *Course Management Systems* (CMS), on the other hand, include those products whose primary focus is the development and delivery of asynchronous learning environments. CMS typically target educational institutions, offering lower cost and built-in content-creation tools. They generally offer varying levels of student management and progress tracking functionality. They rarely support third party software. Examples of CMS include Blackboard, WebCT, and TopClass.

The third category, *Learning Management Systems* (LMS) includes those environments whose primary focus is the management of learning. They do not provide content development tools but they do support third party courseware. They are extremely scaleable, and content is usually stored in an enterprise-class SQL database. They are relatively expensive and are generally directed towards corporate clients. Examples of LMS include Docent and Saba.

The category of *Total Solutions* includes systems that are indeed complete online learning packages. These include a learning environment hosted by the vendor. In addition, the vendor may provide content or work with the organization's subject matter experts to develop content. The packages are tailored to meet the needs of each individual organization. Examples of Total Solution providers include eCollege, Embanet, and Convene.

Delivery and *Development Support Tools* are products that are not online learning environments. Rather, these are used to support either the delivery or the development of content. These include tools such as threaded discussion boards, online tests, chat or messaging systems. Examples of Delivery Support Tools include TeamScape, NetSynergy, WebTeach, NetMeeting, WebBoard, and Hot Potato online testing tool. Examples of Development Support Tools include ToolBook II Assistant, and Designer's Edge, an online instructional design support tool.

The category *WWW Publishing Tools* includes products that are used to create Web sites such as FrontPage and Dreamweaver.

The final category *Media Creation Tools* include graphic creation tools such as Photoshop, animation tools, audio and video tools, and virtual reality tools.

Evaluation Levels

During the fourth phase of the eLearning project, nearly one hundred products were categorized using the scheme described in the previous section. The next step was to develop the evaluation criteria for each category. After a through literature review coupled with the knowledge of product types in each category we adapted the evaluation scheme proposed by (Landon, 2001) so that it can be applied to the products in all categories.

The resulting evaluation scheme has three levels: (i) The learner support; (ii) the instructor/designer support; and (iii) the technical specifications.

The *learner support* level concerns with the tools and features available to learners. These include the evaluation of system's capabilities to support learners, such as tools for web browsing, asynchronous sharing, synchronous sharing, and learner management.

In similar fashion, the *instructor/designer support* level focuses on the tools and facilities available to instructors and course designers. These include system's capabilities to support instructors and course designers manage the overall course, lessons, the student data and administrative tasks.

The third level focuses on the *technical specifications* of the systems. These include server platform, client platform, limitations, and exit considerations, as well as pricing policy. All of these evaluation levels contain sub-categories into which the evaluation criteria are organized (Figure 1).

Figure 1. Three level of evaluation proposed for e-learning related products

Level I:
The Learner Support

1. *Web Browsing*
   a. Accessibility
   b. Bookmarks
   c. Multimedia
   d. Security

2. *Asynchronous Sharing*
   a. E-mail
   b. BBS file exchange
   c. Newsgroups

3. *Synchronous Sharing*
   a. Chat
   b. Voice chat
   c. Whiteboard
   d. Application sharing
   e. Virtual space
   f. Group browsing
   g. Teleconferencing
   h. Videoconferencing

4. *Study Support Tools*
   a. Self assessing
   b. Progress tracking
   c. Searching
   d. Motivation building
   e. Study skill building

Level II:
The Instructor/Designer Support

1. *Course*
   a. Course planning
   b. Course managing
   c. Course customizing
   d. Course monitoring

2. *Lesson*
   a. Instructional designing
   b. Presenting information
   c. Testing

3. *Data*
   a. Grading online
   b. Managing records
   c. Analyzing
   d. Tracking

4. *Resource*
   a. Curriculum managing
   b. Building knowledge
   c. Team building
   d. Building motivation

5. *Administration*
   a. Installation
   b. Authorization
   c. Registering
   d. Online Fees Handling
   e. Server security
   f. Resource monitoring
   g. Crash recovery

6. *Help Desk*
   a. Student support
   b. Instructor support

Level III:
Technical Specifications

1. *Server Platform*
   a. RAM
   b. Disk space
   c. Windows NT server
   d. Apple server
   e. Unix server

2. *Client Platform*
   a. Minimum level
   b. Target Level

3. *Pricing*
   a. Start-up cost
   b. On-going cost
   c. Technical support

4. *Limitations of Package*
   a. IMS compliance
   b. Number of courses
   c. Number of students
   d. Number of connections
   e. Other limitations

5. *Extra Considerations*
   a. Options
   b. Exit considerations

Utilization of the Evaluation Framework

During the eLearning project, around one hundred e-learning related products were organized into eight categories described earlier. The products in each category were then evaluated in all of the three evaluation levels. Table 1 provides a sample evaluation table for a few Course Management Systems (CMS). As seen in the table, each CMS is evaluated whether or not it possesses or supports certain functionality. Three possibilities exist:

1. The check mark (v) means, "Yes, the product possesses the feature"
2. An empty cell means, "No, it doesn't possess the corresponding feature nor does it support it"
3. 3rd means, "No, it doesn't provide that functionality but integration of that feature is possible via third party integration."

Table 1 provides a good overview of the results of evaluation of all of the products in the same category. It allows comparison of the products in each category at a glance. Yet, for the purposes of selecting a particular product, one may need more information on how the product supports certain functionality. That is why, the evaluation table is supplemented by a second table that provides detailed review along the categories in the evaluation scheme (see Table 2). This table allows more detailed comparison of the products.

The next step in eLearning project is to develop a Web-based Decision Support Tool. We will also continue to evaluate elearning related products as they become available. Certainly, we may need to update the products already in the database as new versions become available.

Table 1. Sample evaluation table for Course Management Systems Category (names of the CMS are not disclosed)

BEST COPY AVAILABLE

FEATURES/TOOLS	CMS X
	LEVEL I: LEARNER SUPPORT
Web Browsing	
Accessibility	Content can be developed in text -only version
Bookmarks	You can add web pages to your favorites list
Multimedia	Instructors and students can control synchronized multimedia courseware created in Asymetrix Toolbook and Macromedia Authorware. The multimedia authoring tools can be used to create courseware, which contains audio clips, video clips, animations, simulation, learning exercises and tests.
Security	There are two forms of security. Log-in security and class room security.
Asynchronous Sharing	
E-mail	Upon registration student can enter email. Not a requirement
BBS file exchange	Can add files onto Virtual Campus to load files.
Newsgroups	Virtual Campus can be used to share information
Synchronous Sharing	
Chat	Incorporates a text chat
Voice Chat	Voice chat is possible via integration of NetMeeting
Whiteboard	Objects and text from any Windows supported application can be pasted in to the whiteboard and shared by everyone in class. The floor holder can highlight, add, delete, or edit the whiteboard contents. Whiteboard contents can be saved or printed by everyone in class. In addition, instructor scrolling in whiteboard is synchronized on all student screens.

Table 2. Sample detailed review table for a Course Management System

Discussion

In this paper, a comprehensive evaluation framework for evaluation of e-learning related products was presented. The proposed framework had two dimensions. The first dimension concerns the categorization of e-learning related products. A total of eight, mutually exclusive categories were proposed: (i) synchronous learning systems; (ii) course management systems; (iii) learning management systems; (iv) total solutions; (v) delivery support systems; (vi) development support systems; (vii) WWW publishing tools; and (viii) Media creation tools. These categories do not only serve as the basis to evaluate and compare similar products but they also support the selection process. For instance, if an organization is rather small and do not have Web design and instructional design teams available, they should not base their online learning solutions on the last four categories. Rather, they should go for ready-made systems in the first four categories. However, if an organization do not have a large budget but do have web design and instructional design support then they may choose to go with the last four categories. The advantage with not using ready-made systems is the flexibility of creating a custom solution for organizational needs. They are cheaper but can prove to be more time-consuming. The analysis of the organizational and technical requirements and capabilities is important in making the initial decision on what kind of online learning solution the organization needs. This solution may come from a specific category as well as a blend of several categories.

The second dimension concerned the evaluation of the products in each category. Three evaluation levels were proposed: (i) the learner support level; (ii) the instructor/designer support level; and (iii) technical specifications. Each level contained a number of subcategories around which the evaluation criteria are organized.

The evaluation framework presented in this paper was developed to support the organizations in selecting the best blend of online learning solutions that meets their organizational and technical

BEST COPY AVAILABLE

requirements. There is no one 'right' answer but there are simply better or poorer choices based on how well online learning solutions are selected to match both organizational and technical requirements (Jackson, 2001). The basic premise of the proposed evaluation framework was that organizations can make better choices in selecting online learning solutions if they evaluate and compare their options more accurately.

Abstract

This study investigated the use of various forms of computer-mediated communication (CMC) to support the formation of a knowledge-building community (KBC) in teacher education. A KBC involves students working in small and large groups to solve 'real world' problems, and in the process develop skills of negotiation, communication, and collaboration. Emphasis is placed on authentic problems that are linked to a school context.

The findings showed that the students preferred to use forums available to all participants. Also they used the forums in ways that were not anticipated by the authors. Many students made use of other modes of CMC such as e-mail and synchronous forums downloaded from the Web. Also many of the skills we used in mediating face-to-face discussion could be transferred to the on-line situation.

Key words: computer-mediated communication, knowledge-building community, teacher education

Introduction

Once Universities operated on the assumption that information would be stored centrally and scholars would come to this central store of knowledge and collaborate to produce more information but modern, digital information storage and telecommunications allow scholars to access information from any location connecting to the Internet. When information comes to people there are many benefits such as: direct access to a broader range of information; access to learning environments outside normal lecture and tutorial times; greater opportunity for experiencing a variety of instructional strategies including small group discussion and collaborative projects; and exposure to a forum for expressing and sharing ideas (Lockyer, Patterson & Harper, 1999). Some researchers claim that education that is entirely based on such technology contributes to a loss of community. For example, Besser and Bonn (1996) assert that it is difficult to build collaborative relationships among students, but Bonk and Cunningham (1998) showed that technology allows for genuine conveyance of human communication and learners can develop relationships regardless of the reduced cues associated with computer mediated communications.

This study contributes to the research by providing research evidence regarding the effectiveness CMC to foster the development of preservice teacher understanding of the values, norms, and habitual ways of seeing which belong to the teaching profession. This learning process relies on the integration of learners into a community of practice (i.e. the teaching community) and is facilitated through immersion in the discourse of the teaching community (Schon, 1983; Vygotsky, 1978). Such learning processes are "grounded in talk" and can stimulate higher order thinking skills by providing a context and mechanism for explanation, justification and reason (Duffy & Cunningham, 1996, p.181; Oliver, Omari & Herrington, 1997).

A knowledge-building community (KBC) in teacher education

The KBC project provided students enrolled in an initial teacher education course with an alternative pathway to professional socialisation by forming a Knowledge-Building Community (KBC). Such professional socialisation occurs through the transmission of values, norms, and habitual ways of seeing which belong to particular occupations and shape the way that people conduct their work and establish themselves in the larger social world (Schon, 1983; Bowen & Marton, 1998). Some educators claim that distance education technologies cannot support such a process (Weedman, 1998), but we argue that distance education technologies *can support* this process *provided* it occurs within a defined knowledge-building community.

Berieter and Scardamalia (1993) describe a 'knowledge-building community' (KBC) as a group of people who investigate problems. Members work as groups and are engaged in progressive discourse in an iterative process of knowledge building. The Faculty of Education at the University of Wollongong wanted to use collaborative technologies to support the formation of a KBC and the model we adopted consisted of three interacting sources of learning:community-learning (CL) which involved students, university and school facilitators sharing knowledge as a community; school-based learning (SL) which involved the students in authentic school contexts; and problem-based learning (PBL) which involved students working in groups to investigate problems.

Using Computer Mediated Communication to support a KBC

The current study contributes to the understanding of how the students used the available CMC to support problem-based learning and their understanding of the teaching profession. Also, it investigated whether students were prepared to experiment with other forms of CMC if it better suited their purposes. We believed that CMC supplements face-to-face teaching by providing discussion forums that are non-threatening. CMC tools also allow individuals to maintain links with their community of practice and to take advantage of the scaffolding that is provided by a dynamic social context. Such links allow for legitimate peripheral participation (Lave & Wegner, 1991).

The Role of Problem-based Learning in the KBC

Problem-based learning (PBL) is a curriculum development and an instructional strategy designed to challenge students (Finkle &Torp, 1995). Originally developed for medical schools, it provides advantages for both acquisition of knowledge and development of problem solving skills in patient care (Barrows & Tambly, 1980). PBL challenges students to take charge of their education by involving students in small groups to solve 'real world' problems. Emphasis is placed on 'real world' problems that are 'ill-structured' (Gallagher, Stepien & Rosenthal 1992). Such problems: require more information to understand the problem, change as new information is added, require many perspectives to interpret information, and have no absolutely 'right' answer.

The Faculty of Education at the University of Wollongong decided to use a PBL approach to respond to studies that followed-up graduates of teacher education courses. Some studies reported that many students left university with feelings of being under-prepared for life in classrooms and confused by what confronted them when they arrived at schools (Armour & Booth, 1999; Ramsey, 2000). Others reported that schools which employed new graduates reported that a majority were unaware of how school and classroom cultures operated (MACQT, 1998; Ramsey 2000).

The literature about socialisation to the professions (eg Weedman, 1998, p1) contends that "professional socialisation is a complex and variable form of learning, highly collaborative in nature." It involves the transmission of social constructs, language, belief systems and symbolic lives that are unique to the profession (Schon, 1983). Brown and Duguid (1993) argue that this type of learning makes use of knowledge that must be "stolen" - the most important knowledge is that which cannot be taught and students must find ways to steal it from their educational environment.

The approach taken to the KBC course was influenced by financial constraints. One constraint was that we only had sufficient resources to offer the KBC course every alternate semester. Thus the KBC course was not offered students followed the 'mainstream' university course.

The first semester of our KBC course had two parts. The first part ran for five weeks and was designed to prepare students to work in a learning community amd they also developed teamwork skills as they acquired problem-solving skills. Another goal of the first part of the course was to prepare students to be what was called a 'teaching associate'. A 'teaching associate' supports a classroom teacher's work and may help teachers to; prepare and teach lessons, mark written work, read to children, have children read to them, run excursions, conduct sports training, supervise the school yard as well as a host of other functions that emerged as we gained experience with the program.

The second part of the KBC course ran for nine weeks. During this time students attended their host school for two days per week and attended university for one or two days per week. When they were in schools they had two main roles. One was to be an effective teaching associate and the other was to be what we called 'an educational anthropologist'.

The role of an educational anthropologist was to 'live' within the school community and to 'steal knowledge' (Brown & Duguid, 1993) that would help them to develop an understanding of the culture of their schools and of the actions of the children and teachers that they observed. Thus they needed to work with a number of teachers and allied professionals who acted as 'informants' about their profession and the culture of the school. As they gathered this information they would share it with others in their community.

Purpose of the study

The purposes of the study were:

1. To understand how members of the knowledge-building community made use of CMC to developed their understanding of the professional role of primary school teachers;
2. To describe the role that the lecturers took in mediating on-line discussion among members of the knowledge-building community.

The following research questions were posed:

1. How were the available forms of CMC used to develop an understanding of the professional role of primary teachers?
2. What were some of the limitations associated with the use of these communication technologies?
3. Did the members of the KBC use any other forms of CMC?
4. What role did the lecturers play in mediating the on-line discussions?

Participants

This initial study conducted in (1999) was limited to a group of 22 year one primary education students who were enrolled in the KBC course. The age of the students ranged from 18 years to 45 years and gender composition was three males and 19 females. All participants in this cohort were taught to use an asynchronous discussion space (DISCUS) during the 2^{d} week of the session. During the next week they had two additional one-hour training sessions that focused on the use of a private, small-group discussion space and an open forum (public discussion space). DISCUS could be accessed from their home computer, a group of 5 computers available in their university home room or from any of the computers connected to the university network.

Methods

Data were gathered from two sources: student interviews held half-way through the session and at the end of the session; and text downloaded from the various communication technologies used. The original criteria for classifying interview transcripts and downloaded text were based upon the three elements of the KBC community: community learning; school-based learning and problem-based learning.

Data pertaining to the lecturers' role in mediating on-line discussion came from post-session interviews with lecturers and analysis of text that students contributed to the discussion spaces. Names of students have been changed for the purposes of reporting findings.

Results and discussion

The results are organised under the following headings: community learning; school-based learning and problem-based learning. Under each heading the contribution of each mode of CMC is discussed. Finally, the ways in which the CMC were used and the roles the lecturers played in facilitating on-line discussion are described.

Community learning

Community learning (CL) was designed to support students as they embarked upon the other two sources of learning (PBL & SBL). Team building workshops were designed to engage students in learning experiences that allowed members to learn to work effectively with all members of their cohort. To enhance the community learning students were housed in a special 'home room'.

The asynchronous forum (DISCUS) was used to support community discussion. This allowed for individual discussion, intergroup, and intragroup discussion as well as lecturer input.

By the end of the preparation phase the students learnt to use the asynchronous discussion space (DISCUS) and e-mail and Kime and Karen commented.

> *It's been great. I have loved working in groups. I have had the best time. I have found that by working in a friendly environment you learn more.* Kime 31.3.99

> *I don't think I am learning and then I go home and all this stuff comes out. I think where did that come from? We talk. If we have a problem we talk. One of my initial concerns about this course was that my friends weren't doing it and I thought that I would be on my own but just the opposite has happened.* Karen 1.4.99

Several themes emerged. First, it appeared that friendship and community support assisted their learning because they felt comfortable in their environment and learnt through participation in face-to-face as well as via electronic conversation, and KBC class activities. Second, they were making effective use of the communication technology. They said that they had time to think and compose a response rather than quickly react as they often did in face-to-face interactions. Third, students preferred the community discussion space because everybody could contribute and follow all of the threads of the conversations. In response we removed access to the restricted discussion space.

School-based learning

After three weeks in schools the students were beginning to understand that teaching was a much more multifaceted and complex role than they first thought. Lisa discussed her views on the forum and said:

> *I had no idea of the preparation, organisation and behind the scenes work that teachers had to*

do. I have had a respect for the work teachers do during the day, in school hours, but even in this I wasn't aware of the full extent of it ... Lisa 5.5.99

Susan, the most prolific user of CMC commented:

Teachers talk so much in the staffroom about different topics; it really is a collegial atmosphere. It's usually focused on different activities that are happening during the day and how they're going to coordinate them all. They all help each other out with the stuff that's going on. I was never aware of the intense preparation months before hand. My mentor was describing what they do to prepare for their program - all the infants' teachers get together before term starts and work out what they are going to do EACH day for the rest of the term! Each day, so far ahead! I kind of thought you worked it out the night before! Susan 12.5.99

The quotes indicate an increased awareness of teachers' work and similar views were expressed via different modes of CMC. It appears that in a short space of time the students were beginning to appreciate and witness the complex and multi-faceted roles of a teacher. Also, they could access a variety of modes of communication to express these ideas.

In addition students became aware that teaching requires high-level skills and practice is need to develop these skills. Importantly, students were gaining insights that teaching is a life-long commitment and requires life-long learning.

Problem-based learning (PBL)

The function of PBL was to extend student understanding of the professional role of teachers. PBL requires a great deal of honest and open communication and the preparation phase was used for this purpose. As Lave and Wenger (1991) assert the community does not necessarily have to be warm and effusive; instead it can be diffuse, fragmented and contentious and this was the case with several groups involved in this study. The following e-mail from Julia illustrates this point.

Initially I thought that we were unable to communicate effectively, as some people dominated the discussions while other people had good ideas that were not listened to... 14.5.99

Our inexperience in developing suitable problems for students also contributed to some confusion and general intellectual unrest. The first problem developed focused on the teaching of literacy skills to children (5 to 9 year olds). In retrospect we acknowledge that we suggested too many learning outcomes and this contributed to the silence that befell the room when we issued the first problem package. We needed to rethink our approach when we prepared our second problem which focused on the development of multiple intelligences in young children (Gardner, 1987).

Students who were reticent to voice their real opinions in class were more forthright in voicing their concerns through the discussion forum and via e-mail. For example, Susan said:.

I'm slowly dying. I am just so tired that I cannot think anymore. I am a zombie. This whole literacy thing is just so enormous. I hate assignments and I am so sick of this problem.
Susan 14.5.99

The combination of several new factors for the students (i.e the role of a teacher associate combined with the problem assessment task) prompted us to modify the problem so that we covered less material but to a greater depth and Julia's final e-mail about the second problem illustrates this point.

We were able to accomplish the second problem better as we had more knowledge of how to go about it, it wasn't as big as the first one. Julia 28.6.99

The role of computer-mediated communication

During the first three weeks, students made two to three entries per week. Of these, 13 used on-campus computers and the remainder used their home computers. The prolific users were those who had home computers and five owners of home computers were contributing up to 10 times per week. We allowed students continuous access to the forum during session breaks and into the next year. The rate of use remained much the same even though the students were no longer working as an 'official' knowledge-building community.

Students also made use of group and individual e-mails, but the asynchronous discussion space was the main means of electronic communication. It contained a total of 572 entries by the end of the first teaching session (13 weeks). During the session entries were printed and read by a research assistant who classified them into temporary categories. These categories were discussed with the research team who looked at the examples provided by the research assistant and made further suggestions. The process was repeated two more times and by the end of our final meeting all members of the team agreed with the categories. As a result the entries were classified as problem-related, school-related, group-related or personal. A large number school-related entries (95) were about how the students or their mentor teachers managed their classes. This finding appears to support the research reporting that beginning teachers are very concerned about classroom management during their initial teaching experiences (MACQT, 1998; Ramsey, 2000).

One group that were widely separated in terms of distance decided to use a synchronous discussion space that they downloaded from web (ICQ). The following quote shows the general tone of their conversation on this forum was about organising group tasks and group meetings.

Being a leader isn't that involved it just means keeping people on task....We'll see what we can get done on Thursday, I feel we need to focus and brainstorm etc and we need a peaceful place to do that. Fiona 4.5.99

At this stage we feel that the following comments can be made about the how students and the lecturers used the forum. However, caution is needed as the current use the forum represents a particular stage in our use of the technology and we acknowledge that this will change, as students and lecturers become more familiar with the PBL process and the technology.

The generalisations that we felt that we could make were:

1. The tone is one of communication about the problem, the school, the groups or assessment;
2. Controversial comments were delivered anonymously. For example one entry on the discus space said:

It is really a shame to see many people being all secretive and competitive. Please make an effort to try to limit the competition. We are all filling the vessel of information together..Anonymous 7.5.99

One member of the lecturing team was 'lurking' in the background and he took the opportunity to mediate the discussion. His entry follows:

...I think that it is healthy that we have a vehicle (discus) to express our comments publicly be anonymous or not. It is good that there are different perspectives on what we are doing and it is important that we stay open minded to hear these perspectives. Hoban 11.5.99

3. Without direction little deep knowledge-building happens through these modes of communication. We soon learnt that monitoring wasn't enough and that we had to contribute regularly, otherwise the discussion would go off at 'tangent' and deal with peripheral rather than core issues. Further, we feel that the strategies we used (e.g. encouraging contributions through positive reinforcement, allowing the debate to run until the discussion was peripheral, re-directing discussion, summarising points of view) mirrored those that we would normally employ in a face-to-face situation;

4. Initially, access to the technology at home restricted students as at least one person from each school group was not connected to the Internet at the start of the session. At the end of the year all had a home connection to the Internet;

5. CMC was a support and a catalyst for other modes of communication such as small group face-to-face meetings (formal and informal), large face-to-face groups (formal meetings at university) and numerous telephone conversations (informal).

Conclusion

We feel that the KBC concept supported by computer-mediated communication has contributed to the professional socialisation of students by addressing four issues. First, it has helped students to define the profession in which they will work and to realise that they are responsible for the development of the knowledge and skills needed to become a member of the teaching profession. Second, they have developed an understanding of the professional life of teachers and the nature of teachers' work. Third, they have come to realise that there is a body of knowledge that they need to access in order to be educated about the profession, and finally they have developed a sense of professional identity.

The combination of learning from three interacting sources of information of a Knowledge-Building Community (KBC): community learning; school-based learning and problem-based learning have enhanced the process of professional socialisation. Also the evidence from the forum, written assignments, interviews and school visits suggests that the KBC process helped students to develop an understanding of the following: norms of service, specialised 'teacher' knowledge, teacher autonomy in exercising professional judgment, teacher autonomy in setting educational requirements and standards of service, and the existence of a code of ethics of the profession. They have also learnt about the professional life of teachers - the language of the profession, belief systems, symbolic lives. Also by performing a professional role in schools they have developed some sense of professional identity.

We also learnt that when students use computer-mediated communication in a KBC they can be very creative and forthright in sharing opinions and ideas. However, like face-to-face conversation, they can deviate from intended pathways and lecturers need to continually monitor the discussion and provide input at appropriate moments – just establishing the community forum is not enough.

The Lord Kelvin Project: Middle School Science for the 21st Century

Sebastian Foti, Ric Ledbetter, Fred Taylor, Ebraheem Al-Kazemi
The Athena Group, Gainesville Florida

Abstract This paper introduces and reports upon lessons learned during the development phase of the Lord Kelvin Middle School Science Program. For the past two years, we have been developing a set of tools to help middle school students learn science in a way that uses the full power of today's technology. Lord Kelvin is a robust collection of science activities, organized in modules, that incorporates probeware, sophisticated simulations, multimedia support for instruction, multiple assessment components, and comprehensive reporting tools. The activities bridge the gap between traditional and high tech science. The project, funded by the National Institute of Health joins the talents of a high tech engineering firm with experienced instructional designers to produce a unique learning experience for middle school students.

Introduction

Everyone envisions a future in which workers will use electronic tools to help them carry out the tasks for which they have been employed. It is often difficult to predict what these electronic tools will look like, yet educators feel obliged to establish curricula designed to develop students' technological skills. We believe that this is the wrong approach. Rather than focusing on technological skills, the Lord Kelvin Experience *assumes* the technology, while helping students learn how to learn. This is easy to say, but how is it accomplished? All learning involves gathering information, organizing the information, and operationalizing the information, that is, bringing the newly acquired knowledge to bear on a task. Living in the information age means that information will be (and is) coming to us rapidly from multiple sources - TV, radio, text books, expert commentary, our friends, in multiple ways - video, audio, text, word-of-mouth, first hand experience. Collecting, organizing, selecting and reporting information and the knowledge distilled from it is a formidable task. The Lord Kelvin interface is designed to optimize student performance in these areas. The interface provides a consistent, predictable system to manage multiple sources and channels of information and experience for students as well as teachers. The interface also allows the level of learning to be customized so that students can "ramp up" to more challenging modes of inquiry. Although it is very sophisticated, in a very short time the interface becomes transparent, allowing the student to focus on content and process issues.

The development of the Lord Kelvin Science Program, which has been funded by the National Institute of Health, has been guided by some basic pedagogical beliefs and principles:

> Through a tight interaction between a knowable curricular structure and a consistent user-interface, a learning environment can support inquiry from multiple perspectives using multiple learning models.
>
> Though students may require different levels of guidance, they can understand and relate to the complexity inherent in the study of modern science.

> Assessment of student accomplishment should be multifaceted and relate to context sensitive information as well as global scientific principles and educational standards.
>
> Teachers can and should take an active role in modifying and/or developing the educational tools their students use to learn. Since teachers are under severe time constraints, powerful editing tools should be at their disposal.

Development began by isolating specific science topics addressed by the National Science Standards but not adequately addressed by current science programs. We then began work collecting, selecting, and developing educational components, or *modules*, centered on the following aspects of each topic:

Background Information
Learning methodologies in three dimensions: a step-by-step model, a guided model, and a task specific free-inquiry model
Hands-on experimentation
Simulated experimentation
Multiple types and levels of assessment
Video and audio clips related to instructional aspects of the component
Multimedia clips related to content

Simultaneously, we began designing and developing an interface (see Appendix) that would provide consistent access to each of the above elements, in a way that would follow and expand upon current usability principles for educational software.

Structure of the modules

The Hook. Each module contains a "hook" or question to motivate and stimulate the student to carry out the investigation. For example, we introduce the debate about cell phone radiation by investigating exactly when cell phones produce radiation.

The Challenge. The challenge is a more specific goal statement. The challenge sets up the investigation and provides motivational cues to help the student get started.

Background information. Each module contains a variety of information related to the concept, and larger scientific principles related to the core concept. The information is organized in a context sensitive way, and relates directly to the investigation at hand, but also offers the student a chance to explore the concept in depth. A typical background session might involve reading about generic science strategies, investigating core content, browsing selected readings and examining other resources related to the core concept.
Methodology. The investigation is conducted using one of three models depending on which learning strategy has been chosen by the instructor. In the step-by-step approach, a "cookbook" methodology is presented for the experimentation. In the guided approach, a less specific

procedure is specified. Finally, in the inquiry approach, statements related to the goal state are given which motivate students to conduct the investigation

Experimentation. To carry out this investigation, students rely on a system of probeware we have developed which measures radiation in the 2.4 Gigahertz range. Each module has probeware associated with it, which has been specifically designed for this program. The probeware is programmable, and over the course, students should begin understanding how to interact with programmable electronic tools. Data collected by the probe may be displayed in a variety of formats, selectable by the student. Students may also use a simulation that simulates the use of the probe. When using the simulation, the data output is collected in precisely the same way as the as the output from the probe.

Assessment. The assessment element includes multiple approaches to assessment and addresses misconceptions, content and process knowledge, and application. Wherever possible, student assessment is encouraged, and student's assessment abilities are developed throughout the program using a variety of strategies.

Other Features. The Lord Kelvin environment contains an elaborate glossary. Any word found in the glossary appears to be "hot" in any system window. Clicking on the word delivers the glossary, and in addition, a series of games designed to reinforce memorization of vocabulary are available. Modules often contain videos that illustrate how to conduct an experiment, or show some application of the concept. Of course, diagrams, charts and other activities are used to explain, analyze, and compare data in a variety of contexts.

Brief overview of the interface

One of our self-imposed prime directives in interface development was to reduce or minimize the cognitive load placed on the student when accessing our materials. In other words, we were anxious to develop an environment in which windows didn't "pileup" requiring the student to move, close, manipulate and otherwise tend to the clutter on the desktop. We decided to create a series of fixed windows that would slide into place when information was requested. We have integrated the windows with the content by using specific windows for the same type of information across modules. When students request to see a module's *Challenge* component, it always appears in the same window. Each window has a set of context sensitive tools relating to activity in that window. Thus, a student can copy, print or save information in the window as well as apply tools such as rulers or stopwatches to the activity in the window. The student requests to view a window through the use of a "Personal Study Instrument" or what we call a PSI tool. The PSI tool always appears in lower right of the screen, and is a control center that allows a student to direct the flow of information to the screen and within the learning environment.

The PSI Tool not only helps the student navigate from one learning experience to another, it provides a motivated teacher with a concise, straightforward approach to designing lesson modules. To a teacher, the PSI tool represents an organizer, an interactive table of contents for each lesson module. Each lesson component will be "launched" from the PSI tool. If a teacher feels that a component of a module is inappropriate for his or her students, using the PSI tool editor, they may "inactivate" that access button from the PSI menu, thereby removing the button from the PSI tool. If the teacher prepares additional information about a lesson module, the teacher may "link" that information to the lesson by creating a new button in the PSI tool. In this way, teachers can customize Lord Kelvin modules. In fact, using the PSI tool editor, teachers can assemble entirely new lesson modules from materials they have previously prepared.

Any teacher who desires to create new Lord Kelvin modules can do so by creating a PSI tool to address the various aspects of the module being designed. Doing so, the teacher combines lesson planning with lesson material documentation. Creating buttons and button sets for the PSI tool gives the teacher a new metaphor for thinking about lesson support. In addition, the PSI tool provides a method to differentiate content that supports different learner groups. Even if the teacher chooses not to author modules, modules may be customized. All packaged Lord Kelvin modules, for example, support learners at three levels: (1) Cookbook - a step by step approach to science investigations (2) Guided - a mode which includes a clear statement of the problem along with ideas about how to solve it, and (3) Inquiry - a mode involving a more ill-structured problem statement, and challenges that may have no cut and dry solution. The teacher can easily choose which level is appropriate for his or her class, group or individual student.

We decided to develop program graphics, media, and simulations using a photorealistic model. Although some early research (Dwyer (1978), Travers & Alvarado (1970)) showed that realistic representations contained too many irrelevant details that interfered with learning, others (Berry, L.H. (1991), Hannafin (1987)) believe complexity to be a crucial factor in the visual learning process, and that photorealism supports it. Although Heim (1998) suggests that computer users are polarized about photorealism vs. pure fantasy in virtualization, initial reactions to our photorealistic simulations were more positive than reactions to two-dimensional models. The project will generate a doctoral study related to this decision, as well as to others in our design.

Interaction between module components

In Lord Kelvin, a learner examines a concept or elements of a concept from many perspectives. While it is sometimes true that in the Lord Kelvin environment the same content will be addressed using different information channels (text-based readings and video, for example), it is equally likely that the same content will be addressed in a different context or learning mode. For example, since middle school students often have trouble choosing appropriate graphing strategies, Lord Kelvin modules incorporate activities that address graphing both implicitly and explicitly. In addition to a text-based reference about graphing, students will have to make decisions about graphing types when doing real experiments and when doing simulated experiments. The decisions about graphing interact with the students understanding of how data is received from a probe, and in many cases how they have calibrated the probe. The interplay between math and science concepts and between the various elements of the module strengthens understanding. Simulations combined with real-experimentation offer students the opportunity to explore a wider range of variables more rapidly.

In some cases, the simulations used in our program are virtual representation of hands-on experiments, in other cases; the simulations are unrelated to the hands-on experiences of the student. Pedagogical decisions about the content (interacting with technical capabilities, of course) have guided our choices in this regard.

Other constraints placed on this interface development, besides our prime directive to keep it simple, involved scalability issues and a desire to be able to deliver the environment in a web context. These issues required much attention, but as the development process continued, the congestion issue reemerged several times and we had to remain vigilant about maintaining simplicity in the interface. It was difficult not to add new windows, or new components that would clutter the student's learning environment. Our commitment to simplicity in the interface has carried over to teacher-centered environments involving module editing, document construction and network activity.

Though out the design and development process, we have witnessed, and promoted a strong interaction between interface elements and learning goals and objectives. In the development of learning software, issues of usability must be coupled with strong pedagogical convictions. In our case, we have promoted inquiry along multiple inquiry paths, from multiple perspectives, in ways that incorporate many approaches to learning. Students are given both mastery and performance oriented goals, similar to those outlined in Pintrich, P. R. (2000). The strength of the learning experience is based on the consistent application of systemic self-imposed usability rules coupled with robust lesson development. Students will be offered a consistent, comfortable learning environment in which to explore complex scientific relationships. It is our hope that the students' performance will be augmented by the software based inquiry tools and consistent environment we have constructed for them.

Summary

The Lord Kelvin Experience encourages scientific inquiry by involving the learner in several activities that address a single concept from multiple perspectives. For example, a typical module might include a virtual investigation employing a simulator, a hands-on investigation using a state-of-the-art probe with a video segment explaining how to set up the experiment, a reading with comprehensive background information, a glossary with context sensitive help in the form of educational games, a motivational "hook" delivered by a computer agent to get the student started, and eight or nine assessment tools designed to help the student and the instructor assess prior knowledge, conceptual understanding, process and technological skills, and potential applications of the core concept. In order to carry out a robust examination of the concept at hand, the student must be able to navigate within the module from one activity or information source to another, sometimes compiling information, making graphs, and collecting data along the way. The PSI Tool, or Personal Study Instrument allows the student to navigate freely within a Lord Kelvin module. At any point, the student can employ the Notepad to save pertinent information about the concept being studied. Ultimately, the student may transfer and edit the information gathered to make a persuasive final report. Sophisticated reporting tools make this task easier.

The student working in the Lord Kelvin environment is able to employ, apply, and interact with powerful learning tools that help augment the study process at all levels. Teachers working with Lord Kelvin can freely modify any learning activity and is encouraged to create new activities within the environment through the use of built in editors.

Our goal was to develop a robust teaching and learning environment that would replace dozens of software tools in a way that would allow a short learning curve. Further, we wanted to bring the study of science into alignment with the science principles that students interact with everyday. Although we have included some traditional experiments in the project, many of the inquiries involve modern electronic and scientific curiosities, such as cell phone radiation and laser applications. As students become familiar with interactive, programmable probeware, they will begin to understand how to align their tools with their investigative requirements and goals to augment their performance. By working with simulations, they will interact with the variables affecting their results. It is our hope that students investigating modern phenomena using modern tools will recapture the wonder and curiosity upon which every true scientific investigation builds.

Aligning Theory and Web-based Instructional Design Practice with Design Patterns

Sherri S. Frizell and Roland Hübscher
Department of Computer Science and Software Engineering
Auburn University, USA
{frizess, roland}@eng.auburn.edu

Abstract: Designing instructionally sound web courses is a difficult task for instructors who lack experience in interaction and web-based instructional design. Learning theories and instructional strategies can provide course designers with principles and design guidelines associated with effective instruction that can be utilized in the design of web-based instruction (WBI). However, it can be difficult, especially for novice course designers, to operationalize these theories and apply them to the design and development of specific web courses. Effective design methods for WBI that focus on student learning are needed. Design patterns have emerged as a means to capture design knowledge and present design solutions to designers. We believe design patterns can be used to effectively support novice designers of web-based courses. This paper discusses how design patterns that capture pedagogical principles and good design strategies can be used to support educators in designing instructionally sound web-based courses. A design framework for WBI is presented and the resulting pattern language is introduced.

Introduction

The World Wide Web (WWW) has become one of the fastest-growing mediums for the delivery of distance education. With entire degree programs now being offered online, instructors from a variety of academic areas are developing instructional materials for distance learning programs. Many of these instructors are novice web designers and have received no training in interaction and web-based instructional design (Braxton, 2001; Tennyson 1995). The need for design support is a major issue in the design of web-based instruction (WBI) as the poor design of courses is one of the key problems with learning from the Web (Bork & Britton, 1998; Kessler, 1999). Hirumi (2002) found that novice course designers find it difficult to incorporate the types of meaningful interactions needed in distance learning courses. As a result, courses are often developed by posting large text documents to the Internet, which may present students with a lot of information, but are not effective for student learning (Kessler, 1999). Furthermore, widely used web course management systems like WebCT and Blackboard are indeed just that, course management systems. They provide little support, if any, for effective design of web-based instruction.

The instructional design of course materials directly affects learning effectiveness (Clark 1994; Jonassen, 1988). This is especially true for web-based instruction due to the mere nature of the Internet and the type of interaction it provides. Practices that a good and experienced teacher might automatically encourage in the traditional classroom setting have to be purposefully designed for and supported via the proper design of the web-based course. Discussions in small groups or recognizing the fact that some students are confused by way of their facial expressions are features that are not automatically or trivially supported by a website. To promote effective instruction, web-based courses must be designed with a focus on the opportunities and capabilities afforded by the Web in relation to instructional design and learning theories (Khan 1997, Hannum 1998). However, the theories are abundant and end-users have difficulties in their application to online course materials.

Support for novice course designers through design methods grounded in sound instructional and educational theory are needed. We propose that using design patterns as a mechanism for capturing pedagogical strategies and good design practices can assist educators in designing instructionally effective web courses. Whereas theories can be abstract and difficult to apply, patterns are more procedural and present design knowledge in a way that can be adapted and re-used. Design patterns have traditionally been used to provide design support to novice designers in the fields of architecture (Alexander 1977, 1979) and software engineering (Gamma, 1995), and are now being explored within the human-computer interaction (HCI) community (Borchers, 2001; Tidwell 1999).

This paper presents our approach for providing design support to novice course designers using design patterns. We begin with an overview of design patterns and examine their use for WBI. We then discuss how research from learning and instructional theory can be used to provide an appropriate design framework that supports the development of design patterns. Finally, we describe our efforts towards the development of a pattern language for web-based instruction and present an example pattern from the language.

Design Patterns

A design pattern can be defined as an approach for capturing and presenting design knowledge to solve problems. They act as a design aid to dissimilate expert knowledge to novice designers. Design patterns usually exist within a language with other patterns addressing design problems in that same domain. Although the format can differ, patterns usually contain many sections:

1. The **Pattern Name** identifies the pattern and provides a way to communicate about the pattern.
2. The **Problem** describes when to apply the pattern explaining both the problem the pattern is trying to solve and the context surrounding it.
3. The **Solution** describes the elements that make up the design explaining to the user how to solve the problem.
4. The **Forces** describe the results and trade-offs of applying the solution.

Other elements that are often included in a pattern include an *example* of the solution, a list of *related patterns*, and a *rational* section explaining how or why the solution solves the problem. The information contained in a pattern is not new or invented. This information comes from looking at examples of successful design solutions or at expert design knowledge and experience. Patterns provide a way to represent this knowledge in a form that supports inexperienced designers. Although patterns are of great benefit for novices, they are still very useful to experts as patterns can be used to communicate interesting design ideas to other experts.

Patterns were first used in the field of architecture (Alexander 1977, 1979) to support the design of modern architectural structures. This work resulted in a pattern language consisting of 253 design patterns that present solutions to problems encountered in architectural design. The patterns range in scale from patterns for the distribution of towns and neighborhoods to houses and rooms. An example is the *Bus Stop* pattern, which addresses problems concerning the design of a bus stop. The *context* is any town who public transportation is based on buses, and some of the *forces* are that bus stops need to be easy to recognize and people waiting there should feel safe. The *solution* suggests to the designer to build bus stops so that they work together with other activities in the area such as a newsstand or coffee shop. An illustration of the solution is also provided for the designer. The goal of this work was to support both architects and the general public in designing quality towns, neighborhoods, and homes.

Building upon this work, design patterns have been used within software engineering to document design experience for less experienced software developers in the areas of object-oriented technology (Gamma et al., 1995). These patterns have also been used as an educational tool to teach computer science curriculum and to document successes in teaching object-oriented technology to undergraduate students (Gelfand, 1998; PPP 2000).

Design pattern usage is a relatively new idea in the field of HCI to support the design of user interfaces and usable systems (Borchers, 2001; Tidwell 1999). Traditionally, design guidelines have been used to capture design knowledge to support designers within this domain. However, guidelines have come under scrutiny on their ability to actually solve design problems. Mahemoff (1998) contends that guidelines are not very useful in solving specific design problems because they are too abstract to apply to specific design projects. Others point out that with guidelines, it is difficult to see the actual problem addressed by the guideline, whereas a pattern makes both the problem and the context explicit (van Welie, 2000). In addition to solving problems, pattern languages are also useful for helping a designer to find problems within his design by helping to raise the designer's awareness of potential problems. This can be a powerful design and training aid for a novice designer.

Design Patterns for Web-based Instruction

Sound pedagogical practices are not often integrated into the web-course design and authoring process (Hannafin, 1997; Janicki 2001). The difficulty lies in operationalizing the guidelines and principles from the various theories into the design and development of instruction. Principles such as "design courses that are motivating" or use "exploratory-based instructional strategies" are quite abstract and difficult to apply to the design of specific courses. Trying to use and apply principles such as these suffers from of the same type of problems as guideline usage within HCI design. Design patterns can provide a mechanism for capturing pedagogical strategies and good design practices in a way that supports novice course designers in designing instructionally sound web-based courses. A pattern-based design approach to WBI can support the alignment of educational theory with actual design practices. With design patterns, we can utilize a theory-supported, but problem-solving approach to the design of web-based courses.

Towards a WBI Pattern Language

We have been working towards the development of a pattern language for web-based instruction. Our goal is that this pattern language will support novice web instructors in the design of quality distance learning materials for students. As a foundation for the language, we use learning and instructional theories to develop an appropriate design framework for WBI. Research from this body of literature identifies a number of principles associated with effective instruction that can be utilized in the development of design patterns that solve web-course design problems. The resulting design framework shown in Table 1 merges key design concepts from both behavioral and cognitive theories on learning (see Kearsley, 2001 & Mergel, 1995) with research from web-based instructional design models (Duchastel, 1997; Kearsley, 1999). As advocated by Morrison (2001), we adopt a view that it is good to incorporate both behavioral and cognitive approaches to learning in the design of web-based instruction in order to reap the benefits of each to address diverse student populations.

- Provide Structure to the learning process
- Provide a Foundation for learning
- Specify Learning Objectives
- Encourage Student Participation
- Give Feedback and Guidance
- Provide Support Aids
- Encourage student Expression and Reflection
- Design for Interactivity
- Build Learning Communities
- Include Authentic Content and Activities
- Provide Problem Solving Activities
- Provide Multiple Perspectives and Representations

Table 1: WBI Design Framework

We have an initial language of about twenty design patterns that embody the design philosophy represented by the framework described above, but from a problem-solving perspective. The language addresses design problems from overall course presentation to specific student learning activities As shown in Figure 1, we have chosen a categorization for the design problems in WBI based on three elements: *content*, *learning activity*, and *learning support*. This model or categorization for design problems in web-based instruction builds upon the model presented by Oliver (2000) for the design of WBI based on principles from situated learning theories. Patterns in the content category help with the presentation and structure of the learning process. Learning Activity Patterns provide solutions to problems concerning activating and enhancing student learning. Learning Support Patterns address problems with proving support to web students.

Figure 1: WBI Problem Space

The format used for writing the patterns contains the standard pattern elements such as *problem*, *context*, *solution*, and *forces*, in addition to a *rational*, *related patterns*, and *reference* section. The reference section is used to validate the information contained in the pattern and to give the designer additional resources. An abbreviated pattern from the language is provided in Figure 2. This pattern named "*FAQ*" addresses how to handle students' problems or questions. The solution given by the pattern is a strategy for providing immediate feedback for student inquiries. Although not shown here, patterns also contain an example of the solution given by the pattern. Space does not permit us to present each pattern in detail. However, the following few pattern names and descriptions are provided to give an idea of the range of problems addressed in the language.

> *Learning Community:* Addresses the isolation problem experienced by some web-based students. The problem is how to facilitate a sense of community for online students. The pattern's solution supports the creation of collaborative learning communities.
>
> *Discovery Orientation:* Addresses the disorientation that can be experienced by students in courses that provide little organization and link to many additional web sites. The problem is how to help students orient themselves within the learning space.
>
> *Teamwork*: Addresses the problem of coordinating teamwork over the web for group projects and assignments. The pattern solution's encourages the instructor to take the role as facilitator to assist students.

BEST COPY AVAILABLE

Pattern Name: FAQ

Problem: Students have problems and questions that necessitate quick responses.

Context: Any web-based course consisting of students whose location may be different from that of the instructor's location or who are novice web students.

Forces:

- Emails from students can quickly fill up an instructor's email account.
- Multiple students may have the same question.
- The time involved in answering questions can be substantial.
- Student's work hours may be different from instructor's hours.
- Students want quick responses.

Solution: Create a document in the course that contains a list of questions along with the answers. Include questions that have been already asked by students and if you have taught the course before, you can include common questions from previous students. It would also be beneficial to include any questions that you anticipate students may have. To insure that students utilize this document, encourage them to refer to it as a resource tool for them to address many of their concerns.

Example: *(Omitted)*

Rationale: It is frustrating for students to have questions and not be able to get immediate answers to them. FAQ provides a mechanism for handling student questions that gives them immediate feedback.

Related Patterns: *Feedback-Loop*

Figure 2: WBI Design Pattern

A pattern language for WBI stills allows for some creativity in the design of instruction, as they do not remove the role of the instructor from the instructional design process. As Vlissides (1998) points out, design patterns do nothing to remove the human from the creative process of design. Design patterns serve to support a possibly inexperienced, but otherwise capable person. Our goal is that novice web-course designers will become better course designers by using the pattern language.

Conclusion

Design patterns have emerged as a way to capture knowledge to present design solutions to novice designers. We have presented our efforts towards the development of design patterns and a resulting pattern language for web-based instruction to support novice web-course designers. We believe a pattern language for WBI based on principles from instructional design and learning theories can support the design of instructionally effective web-based courses. We have coupled this pattern language within a design environment for web-based instruction that scaffolds the process of finding, selecting, and applying patterns to course design problems (Frizell & Hübscher, 2002).

The Methodology for Reuse of E-Learning Resources

Takashi Fuji, Takeshi Tanigawa
Faculty of Business Administration and Information Science
Hokkaido Information University
Japan
fuji@do-johodai.ac.jp, kt@do-johodai.ac.jp

ABSTRACT: This paper describes a domain-specific repository based on the methodology for e-learning systems development. The methodology, which is based on information engineering and object-oriented technology, is used to support navigation for courseware development, designing the curriculum of e-learning components, and e-learning resources management. A repository-based approach is key to support of e-learning development and reuse of e-learning resources such as application frameworks and components. Through the structure of the repository such as meta-model / model / object-base and by use of object-oriented modeling, it is constructed for reuse by systems analysts and subject matter experts. Systems analysts can build new models by reusing meta-model and models for their target system. Subject matter experts can develop their courseware by reusing models and object bases for their e-learning. And, by using CORBA architecture, we developed the distributed e-learning systems development environment.

1. Introduction

The reuse of instructional materials is developed by some projects such as ARIADNE (ARIADNE , 2001) and SCORM (SCORM, 2001). The purpose of this paper is to present the methodology for the reuse of e-learning resources such as components (included instructional materials) and application frameworks. For the systems analyst, Repository-Based Environment for Computerized Courseware Analysis (REBECCA) (Fuji 1997) enables the reconstruction of e-learning systems by reusing application frameworks such as Audio Visual and Adaptive Learning system by Oneself in Network (AVALON) (Fuji *et al.*, 1994) and Collaborative and Multimedia Environment for Learners on Teams (CAMELOT) (Fuji *et al.*, 1996). For the subject matter expert, WWW-based Curriculum Authoring with Thesaurus (WEB-CAT) (Fuji and Hoshihara, 1997) enables the construction of the intended curriculum with collaborative work through WWW, while REBECCA provides a means of course navigation, the reuse of instructional material, and target system generation.

There are two learning styles incorporated in e-learning systems: individual learning environment, and collaborative learning environment. We have developed prototypes of an application framework, AVALON (for the individual learning environment) and CAMELOT (for the collaborative learning environment). These application frameworks are constructed by use of object-oriented technology, and are stored in the domain specific repository called REBECCA for reuse. Repository-based methodology is derived from information engineering (Martin, 1989). With regard to the components in e-learning systems, there are instructional material, curriculum, and pedagogy. We have developed a prototype called WEB-CAT for developing curriculum through collaborative work with a domain specific repository and WWW. And, as the REBECCA is constructed by an object-oriented technology, it is easy to adapt Common Object Request Broker (CORBA). E-learning components and e-learning frameworks of the distributed REBECCA correspond to a CORBA application object, and these components use CORBA services for searching for distributed object reference by name or for creating new objects.

This paper is organized into two sections: Section 2 outlines the framework in e-learning systems; Section 3 describes the distributed e-learning systems development environment with CORBA architecture.

2. Framework and Component for E-Learning

The reuse approach is based upon and relies on the concepts that reusable software components are produced and stored in a repository. There are two main types of object-oriented components:

(1) solution-based inheritance hierarchies, and
(2) domain-based frameworks

This framework is based on domain-based frameworks such as CAI systems, and we use a framework in the sense of a skeleton application that the developer can adjust with it. The term "component" is often used interchangeably. The software component is a physical packaging of executable software with a well-defined and published interface (Hopkins, 2000). The following definition of "component" will be used in this section: "core elements that compose an application framework."

2.1. Methodology for E-Learning Systems Development with Repository

In software engineering, structured techniques are applied to one project, whereas in information engineering, structured techniques are applied to the enterprise as a whole or to a large sector of the enterprise. Information engineering techniques encompass those of software engineering in a modified form. Information engineering has been defined with reference to automated techniques as follows: an interlocking set of automated techniques in which enterprise models, data models and process models are built up in a repository and are used to create and maintain data-processing systems. The repository is a key technology in information engineering, and it steadily accumulates information relating to the planning, analysis, design, construction and, later, the maintenance of systems.

The field of instructional design was initiated by the United States Department of Defense during World WarII to improve the efficiency of certain types of high level technical training programs such as pilot training (Reiser, 1987). The systems approach is a step-by-step procedure for solving problems. It has been applied to educational problems at all levels, from education in general, to training for a specific target population. In instructional design, the systems approach is sometimes referred to as instructional systems development. There are numerous models demonstrating this approach. Although the models differ in detail, such as the number and sequence of steps in which specific components are grouped, the common basic steps are grouped into the following five categories: analysis, design, production, implementation, and evaluation.

The methodology of REBECCA is based on that of information engineering and instructional design. The characteristics of this methodology are as follows.

- Object-oriented repository for managing e-learning systems resources
- Reuse for e-learning systems framework
  individual learning, collaborative learning
- Reuse for e-learning systems components
  instructional material, curriculum, pedagogy
- Navigation for courseware development
  analysis, design, construction

2.2. E-Learning Frameworks

The e-learning frameworks used are: AVALON for the individual learning environment and CAMELOT for the collaborative learning.

AVALON

The AVALON e-learning framework is a multimedia intelligent tutoring system. The system provides adaptive instructional units and pedagogy suited to the individual learner's understanding. The system also provides multimedia instructional units, such as video, voice, text, and image data, suited to each individual learner's characteristics. This framework, composed of pedagogy, a learner model and instructional material information, was used as a base. In order to adapt the following two functions, i.e., a function for dynamic representation of multimedia instructional material corresponding to the comprehension level of each learner and to the media characteristics, and a function for interactive response to questions from learners, we developed an instructional object in which the multimedia instructional material and knowledge expression of instructional material were encapsulated as an instructional object.

CAMELOT

The CAMELOT e-learning framework is a collaborative learning support system. The learning process is based on a nominal group technique. The system facilitates collaborative learning navigation, group discussion, and remedy of collaborative work solutions. The pedagogy is a combination of rule based reasoning and case-based reasoning. The system can remedy learner's basic mistakes using rule-based reasoning. And also case-based reasoning can present analogous solutions to learners for deeper understanding. In the business systems design environment, there may be more than one solution to any given problem. For example the data model will be different depending on the perspective of each individual leaner.

Thus, collaborative learning systems are very effective in this domain. By using CAMELOT, each learner learns how to analyze through case study and how to cooperate with his or her group in problem solving. Learners come to a deeper understanding from using CAMELOT than from studying independently, because of shared discussion, tips from other learners, and examinations, and review of one another's works.

2.3. E-Learning Components

As domain specific components in elearning systems, there are the instructional object, curriculum object, and pedagogy object that compose e-learning application framework.

Instructional Object

An instructional object is an extended instructional unit. An instructional object is composed of a multimedia object and a knowledge object. A multimedia object incorporates multimedia instructional material, such as text, image, voice, and video. A knowledge object incorporates the knowledge representation of instructional units, such as semantic network, rule-based reasoning, and case-based reasoning. An instructional object is used for components when subject matter experts design courseware.

Curriculum Object

A curriculum object is related to instructional objects and selected by pedagogy objects. A curriculum object is structured using a thesaurus. This object is composed of a superordinate concept, a subordinate concept, and related concepts.

Pedagogy Object

A pedagogy object is composed of three tiers such as planning strategy, learning strategy, and action objects for strategy. The basic concept of the learning strategy is based on Gagné's accumulated learning model (Gagné, 1985). The learning strategy is composed of "problem solving", "rule learning", "concept learning", "multiple discrimination learning", "verbal association", "chaining", "stimulus-response learning", and "signal learning". Subject matter experts can design their pedagogy for CAI systems by combining these pedagogy objects.

3. Distributed Environment with Repository

Since the Internet is used worldwide, the global learning environment is also changing to incorporate use of the Internet. In many types of organizations, such as universities and private enterprises, subject matter experts are developing various types of courseware; each site can be connected to the network and they can find a variety of courseware. However, they are not able to use courseware for reuse, because the various types of courseware are developed and executable from different platforms such as Pentium, PowerPC, SPARC, and so on. For the common use of the courseware through the Internet, the distributed heterogeneous development environment is required.

3.1. Utilization of Distributed Object Technology

CORBA is an industry-wide standard for creating distributed object systems. It is a standard that is accessible from many different languages and allows interoperability on various platforms. Using CORBA, a client object can transparently invoke a method on a server object, which can be on the same machine or across a network. CORBA intercepts the call and is responsible for finding an object that can implement the request, pass on to it the parameters, invoke its method, and return the results. The client does not have to be aware of where the object is located, its programming language, or its operating system.

From these characteristics of CORBA, we developed a distributed development environment REBECCA using CORBA. CORBA provides the following benefits in development of distributed development environment:

- CORBA supports many programming language mapping
- CORBA supports distributed computing and object orientation
- CORBA provides interoperability between different vendor's ORBs

3.2. Distributed Repository Using CORBA

As the REBECCA is constructed by an object-oriented technology, it is easy to adapt CORBA. Object Management Architecture (OMA) has four major components, ORB (Object Request Broker), CORBA services, CORBA facilities, and application objects. ORB is a communication infrastructure between distributed objects. CORBA services are a set of system service interface, and include the naming service and the persistent service.

CORBA facilities represent specifications in great detail for the construction of the distributed system. E-learning components of the distributed REBECCA correspond to a CORBA application object, and these components use CORBA services for searching distributed object reference by name or for creating new objects. E-learning frameworks (such as AVALON and CAMELOT) correspond to CORBA facilities that provide domain dependent services. At each site, there is a repository object stored e-learning component such as instructional objects, curriculum objects, and pedagogy objects. The repository object manages the other objects and communicates with the repository object of another site in order to obtain information from and access to resources at another site (Figure 1). The distributed REBECCA with CORBA provides the following functions:

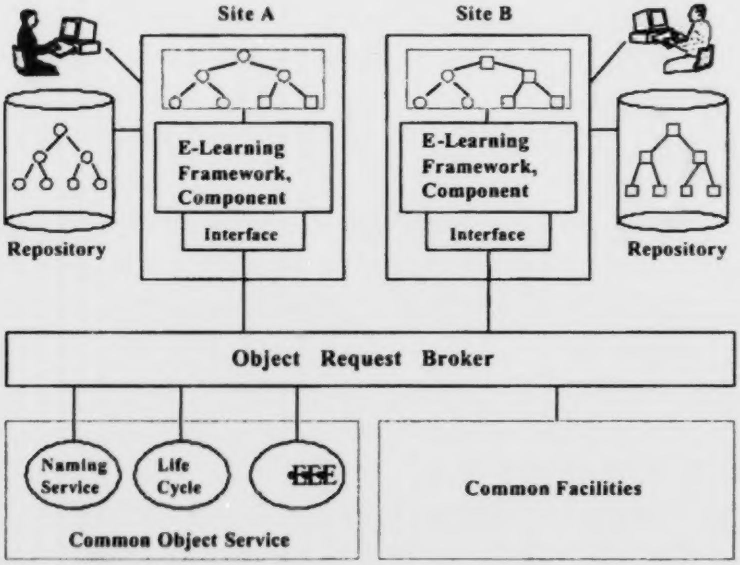

Figure 1: Distributed Development Environment with CORBA

Enables the reuse of heterogeneous and distributed e-learning components

The distributed REBECCA provides methods to treat heterogeneous distributed e-learning components uniformly, so that subject matter experts are able to reuse these e-learning components in developing courseware. E-learning systems can provide adaptive instructional objects on the network.

BEST COPY AVAILABLE

Appropriate site of e-learning components

In using CORBA environment, implementation of e-learning components is encapsulated and can be placed at the distribution site, according to the characteristics of each e-learning component. Therefore, e-learning components can be placed in the appropriate sites. For instance, an instructional object that includes simulation material, which requires a large amount of computer power, is placed at a high performance computer site, and the pedagogy object that requires high inference performance is placed at a computer site with high performance engine for inference.

Management for distributed e-learning components

The distributed repository manages each e-learning components stored in each server site. The distributed e-learning components are able to maintain consistency by means of a global instruction manager (Tanigawa *et al.*, 1998).

4. Conclusion

In this paper, we have described a methodology for e-learning systems development and a domain specific repository for reuse of e-learning framework and e-learning component. The repository is the key to supporting e-learning systems development and reusing e-learning systems resources. Using a three-level structure, such as meta-model, model, object-base, and using object-oriented modeling, REBECCA provides for ease of reuse for systems analysts and subject matter experts. It further enables construction of a distributed e-learning systems development environment using CORBA architecture.

Abstract. We present the design and implementation of an adaptive user model in a web-based virtual university learning environment. It includes techniques that provide personalization features to the educational topic and the exchanging information. In this way it customizes the educational process, served by any virtual university to the personal characteristics of the user. Its distinctive functionality is that encompasses combined adaptation between educational material and well-known communication facilities. In fact the user model consists of different layers that make the environment personalized in two axes. Firstly adaptation is performed separately per activity (member of the profile's higher level) and subsequently knowledge of the different levels is shared through the common lower level and provides further personalization in a more global sense. Personalization obsolescence is also included in the user model in order to prohibit outdated adaptation or intelligence to keep loading the user interface. Furthermore curriculum sequencing provides guidance to the user's learning procedure. Most interesting educational pages for the users -based on their profile- are selectively delivered to them, according to the collaborative filtering method. Finally special care has been taken for the categorization of incoming data streams handled by content and property based filtering.

1. Introduction

A number of virtual educational environments have become available over internet in the past years [24], [22], [23]. Such an infrastructure is also known as "virtual university". It does not have traditional facilities such as campus, classes or library; instead there are web-based services that provide richer functionality and features than their physical analogs [18]. A typical hypermedia application serves the same pages and the same set of link to all users. In order to improve usability, adaptive web-based applications make it possible to deliver personalized views of a hypermedia document to the users with diverse needs and knowledge backgrounds gaining access to the system [19], [22]. A virtual university environment that adopted intelligence in content providing is the Electronic Education Environment [3]. However, these adaptation techniques are focused to a specific service (e.g. educational content delivery or presentation, document topic filtering) and therefore work completely independently in an environment that is supposed to cover a broad set of needs towards the common target of usability and learning improvement. The fruitful design and successful correlation of adaptation capabilities simultaneously for educational material and accompanying supportive services is a task not as simple as one may guess.

In this paper, we describe the design of an adaptive user model and its implementation in an advanced web-based Virtual University environment that encompasses combined and synchronized adaptation between educational material and well-known communication facilities The Virtual University environment has been implemented to support a postgraduate course. It aims to cover the fundamental needs of a student, which is wide range of automatically renewable educational material on any subject chosen under the umbrella of a powerful set of supportive tools homogenized with the user's topics of interest.

The environment at the moment provides training on Internet and Multimedia technologies coupled with a range of supportive tools like communication facilities and common shared workspace. The environment supports personalization features to the educational topic and the exchanging information flow in order to customize the educational process to the learning curve of the student. This is accomplished by acquiring each user's learning model and activity choices. The educational profile is first developed for each student based on a questionnaire and continuously evolves according to the student's choices and activities within the virtual university framework.

BEST COPY AVAILABLE

Key features are the curriculum adaptation [6] and the communicational information filtering [17]. According to the user's knowledge state and interests the former adapts the educational topics' presentation and interconnection, while the latter categorizes the exchanging streams of communicational data items creating this way a corresponding archive for each topic mostly interesting the user.

This paper is organized as follows; section 2 presents an overview of the virtual university framework. The user model is described in section 3. The adaptation mechanisms are the theme of section 4. Section 5 outlines intelligent filtering in data. Results are summarized and future work is presented in section 6

2. Overview of the Virtual University Framework

The Virtual University Environment has been designed as a hypermedia environment addressing users with a vast variety of knowledge backgrounds and targets. Educational material at the moment comprises a variety of courses on the Science of Fine Arts and on Internet technologies. The environment is optimized to include any web-based course that might be available. The courses on all directions are available for every student. In fact it is possible to take any of the courses at every possible combination. However in order to clarify the scale of difficulty for each course there is a short description and a grade (starting from one grading up to four for the most advanced topics) indicating the complexity and the demanding know-how of each one of them. Introductory topics address to novice students and will cover introduction of the Internet, introduction in computer assisted multimedia design etc. Advanced topics cover areas such as advanced web application development, advanced 3-dimensional modeling, etc.

Due to the diversity of the students all courses are personalized and delivered differently to groups of students with common characteristics. An educational profile is developed for each student based on a questionnaire that the student is asked to fulfill after choosing his/her first course to attend. The stereotype of the user evolves while the student performs activities in the Virtual University environment (such activities are the specific course flow that is followed and the students' achievements in tests and projects).

As a sequel the stereotype of the student is used in order to support the system's curriculum adaptation model [6]. In this case adaptation is used in order to perform at first a fundamental pedagogical curriculum sequencing – set by the curricula author -, but, which is most, automatic information pushing of the most appropriate online resources for every student based on its profile. Complementary the technique of link deactivation is used in order to deliver specialized dictionary help for keywords throughout the corpus of a course.

On the other hand an intelligent cognitive filtering is performed, in conjunction with the web based educational material collaborative filtering, to unify the popular communicational (email) and workspace (share space) support within the Virtual University framework, in full parallelism with the fact that every university gives its students an email and some electronic space to utilize with the classes. The communication services in our framework take into consideration the activities of the user in its educational journey within the courses, by deriving some key notions, in order to make a categorization of the information flowing into his/her mailbox. As a result it makes use of the students profile to selectively filter out and categorize its incoming data stream delivering them to proper activity-based topics together with older relative information creating in this way a personal archive.

3. User Profile Model

The user profile records information concerning the user and his knowledge state [4], [1]. This information is vital for the system's operation according to the user's needs and preferences. The method used is an implicit collection of user's actions and it requires minimum user involvement [10]. However, such data is quite difficult to gather because it is not easy to represent the user's knowledge abilities. Moreover, the nature of the Web imposes certain constraints on the system's perception of the user. For the time being, it is difficult and time-consuming to record every user action. In the environment at hand it has been chosen to keep track of the users' traversal path for every visit, the courses', topics' and subjects' keywords and analytical scores in tests, projects and all given grades in general (every user- student has a personal history list of achievements and grades just like all students).

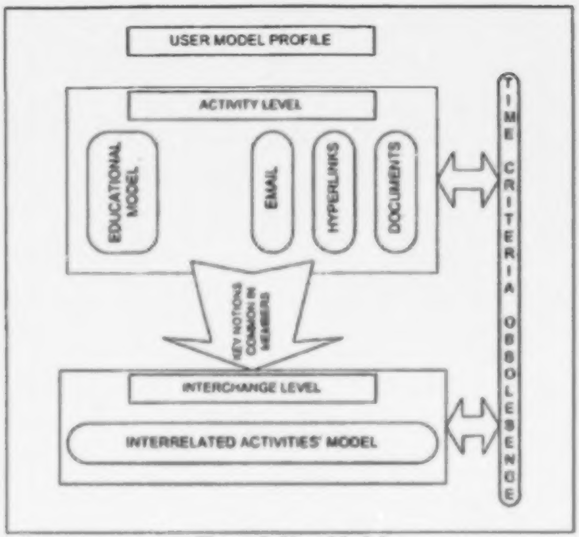

Figure 1: User Model

3.1. Different Levels in the User Model

Due to the variety and diversity of the possible activities of a single user in the Virtual University there is a need for differentiation in the profile itself. In this model the profile contains different levels that represent each activity and a common layer that interconnects the behavior of the user within all the activities together. As a result the profile of each user is both a learning model for the educational procedure and activity representation for the rest services. Specifically the educational procedure is being monitored for the choices (e.g. courses, topics and key notions selection) and the progress (e.g. tests, questions and project achievements). To the other end information exchange within the whole set of communication tools is also recorded (e.g. topics in emails exchange, titles in file exchange and hyperlink exchange). In this way the method creates a set of characteristics (e.g. keywords) that best describe and therefore represent each user's activity.

In the sequel the profile's higher level members are examined for similarity in the characteristics. Each member of the activity level delivers to the interchange level the properties that describe it. In this common pool best-matched properties are considered interconnected and therefore of common interest. These notions that are found common in more than one profile member in the activity level are stored in the interconnection member of the profile in the lower layer. They are used to improve the usability of the environment by interconnecting the activities that they describe in a dynamic sense personalized per user.

The different levels in the profile of the user model make the environment personalized in two axes. Firstly specialized adaptation is performed per activity member of the profile's higher level and subsequently knowledge of the different levels is shared through the common lower level and provides further personalization in a more global sense. The multi-layered profile covers the gap between interrelated adaptive services transforming them to services that associate adaptive techniques towards usability and learning improvement.

Such a case of inner profile information exchange happens whenever a student chooses to attend a course. As a result of this he/she has to perform communication activities for this course. The environment captures the user's educational activity and, after the profile's levels exchange knowledge, it adapts to the new keywords the filtering properties for all communication activities, as email, file and hyperlink exchange. Specifically it redirects the information flow into a new "course" email folder and accordingly makes changes for all activities. Moreover it represents this adaptation within the course environment by activating appropriate link for each course-specific archive.

3.2. Additional Time-based Criteria in the User Model

In order to prevent forgotten and obsolete notions to be maintained in the multileveled profile, it is designed to support short and long-term distinction in users' reactions. The properties that have not been used for a period of time longer than two academic seasons become disabled (though kept in the

BEST COPY AVAILABLE

users profile) indicating that perhaps the user has nothing more to do with this keyword. In the third subsequent season these keywords are being deleted as out-dated for the user. The property obsolescence can be easily transformed so as to be based on the hypothesis that a uniform distribution of property appearance over time is more valuable than others [2]. Although this approach has been neither proved nor disproved, the mere influence of time is a subject of high effect.

3.3. Educational User Model

A learning model that used quite often in the past by other educational systems and which is used in our frame is the overlay model [7]. In this model, the user's knowledge is considered to be a subset of the knowledge perceived by an expert in the learning field. Using this representation, the system presents the educational material to the user so that in the end his/her knowledge will match the expert's knowledge. Another way of modeling the user's knowledge is to use Bayesian networks [14], [21]. These networks probabilistically reason about the student's knowledge state concerning the various knowledge concepts.

4. Curriculum & Course Adaptation

The Virtual University environment consists of an educational framework that uses a curricula adaptation based firstly on the stereotypes, created with the registration's questionnaire, and subsequently mixed with personalization features for each user.

4.1 Curriculum Sequencing

It is recommended that a Web-based educational environment should offer some sort of guidance to the user by presenting the next best course units to be learned [20], [15]. The used type of curriculum sequencing involves the selection of the most appropriate section or topic to be presented next. This selection is made according to the concepts learned by the user indicated in his/her profile. If the user has not learned yet all the outcome concepts of the current subsection (section) then the system will select the topic (subsection) with the least unknown prerequisite concepts. This goes on until the user learns the outcome concepts of all sections of the specific course.

4.2 Collaborative Filtering

The users receive key characterization in the educational profile level according to their interests deriving from their topic accesses. Once a topic (typically a web page) is updated with new material concerning a specific topic, the users who had with certain frequency expressed interest on it in the past are informed about the changes. Thus instead of making the users go after recently updated web pages, it is desirable to have information selectively flowed to them. This is called information filtering [10]. In our case we address the collaborative filtering method, which is the filtering of information based on the advice of others [12]. The users are not only informed of the recently updated topics that they have visited quite often in the past, but also for those topics that have been accessed with certain frequency by other users belonging in the same group of interest with the first ones. In particular, the profile of the users' information needs is captured through their classification in groups of interest.

The classification of the users into subsets according to their path traversal and page accesses will be achieved by using the spectral filtering method developed in [5], [8], [9], [11]. The initial motivation for the development of the method was the discovery of high-quality topical resources in hyperlinked corpora. The full power of the approach is visible when being applied on entities other than hyperlinked documents. In our paradigm we have two kinds of entities: web pages and users accessing them. The precise notion of "access" refers to frequency of access.

Following, we will only outline the method of spectral filtering, as it is applied in our virtual university environment (further details concerning the mathematical details of the approach see [5], [8], [9], [11]). Let S1 denote the set of users and S2 denote the set of web pages corresponding to a specific section. We associate with each ordered pair (i,j) of entities in S1 and S2, a non-negative real-valued affinity A[i,j]. Typically, we set A[i,j] to be a well-chosen function of the accesses user i performs on page j. The A[i,j]s constitute an n x m matrix A, each of whose rows corresponds to users and each of each column to web pages. The entries of the matrices AAT and ATA can be viewed as expressing the similarity between different users and web pages respectively (where the notion of similarity is deduced from similar patterns of accesses). The matrices AAT and ATA are both real and symmetric and their eigenvectors have only real components. Moreover they have the same set multiset of eigenvalues. Let xs1, xs2 be two eigenvectors of AAT and ATA respectively corresponding to the same eigenvalue. We can view the components of each eigenvector as assigning to each entity a position on the real line. We deem the entities with large positive values in an eigenvector to be a cluster, and the entities with large negative values to be a different cluster. Alternatively, we can examine the values in the eigenvector (in sorted increasing order). At the largest gap between successive values, we declare a partition into those entities corresponding to values above the gap, and those entities with values below. From the above discussion it follows that the eigenvectors xs1, xs2 provides us with two pairs of interrelated clusters (c1,c'1), (c2,c'2) where ci corresponds to a group of users with similar web-access patterns and c'i corresponds to the web pages that interest the users in the ci group.

Following the above partitioning process for all the non-principal eigenvectors enables us to group the users into subsets with similar preferences and to map the entities of each subset to the web pages that are of interest to them.

5. Intelligent Filtering in Communication Data

Cognitive filtering characterizes the contents of an incoming stream data and the information needs of potential topic specific pools of knowledge, and then using these representations to intelligently match data streams to pools [13]. Our approach is more a combined content-based and property-based filtering under [16] the common umbrella of the lower profile layer. Cognitive filtering in this environment lies in between filtering based on the content of the incoming streams of the communication data and filtering based on the properties that include more than areas of interest of the user. In this way the environment automatically transforms according to the user needs transparently to the user. The Virtual University performs categorization through filtering in a common sense manner by delivering relative information of data streams together in just one most suitable place per different activity.

In this way each educational course and topic is intelligently possible to be accessed from all topic relevant places within the environment. Adaptive presentation of hyperlinks interconnect all relevant resources such as emails (e.g. exchanged among student partners), files (e.g. shared or distributed by course responsible) and all sorts of hyperlinks from all sections of the Virtual University. It is possible to access all sorts of topic-specific knowledge pools from any of them. We imagined this like the best way to access an email from our own mailbox or have a look in a book from the course's library just while we attend a course (without having to look in all the email list or the library's citations).

6. Conclusions and Future work

In this paper an adaptive user model is presented, designed and implemented within a web-based Virtual University environment, n order to cover the real needs of the learning community. It covers the fundamental needs of a student in a virtual university environment; that is to provide a range of automatically renewable educational material on any subject chosen under the umbrella of a powerful set of supportive tools homogenized with the user's topics of interest. Its distinctive functionality is the interrelation of adaptation techniques used in different activities of the user within the environment, in order to create a picture of the users' behavior as a whole. In this way, it produces a unified characterization of the user. By utilizing this characterization the model extends the adaptivity methods that were used in each activity separately. The user model profile comprises multiple layers of personalization features that interconnect. Moreover time constraints prohibit the profile to become outdated.

Following the above, curriculum sequencing provides guidance to the user's learning procedure. Furthermore most interesting educational pages for the users -based on their profile- are selectively delivered to them, according to the collaborative filtering method. Special care has been taken for the categorization of incoming data streams handled by content and property based filtering.

Our future work aims to develop a dynamic object oriented hypermedia methodology that will incorporate our synthesized adaptive user model. The model will be refined and extended to handle more intelligent and adaptation techniques. A next step for is to be able to personalize more services for the virtual university user in order to attract different academic community members such as researchers. Finally we believe that an extension of our adaptive user model will try to cover the needs of alumni in a virtual university.

The AVENOR VIRTUAL TRAINER PROJECT
a 3D Interactive Training Module on Energy Control Procedures : Development and First Validation Results

Max Giardina, Professor
Faculty of Sciences Education, University of Montreal
Montreal, Quebec, Canada
maxgiardina@hotmail.com

Abstract

This paper seeks to examine the implementation of 3D simulation through the development of the Avenor Virtual Trainer and how situated learning and fidelity of model representation become the basis for more effective Interactive Multimedia Training Situations. The discussion will focus of some principles concerned with situated training, simulation, interaction and immersion which will help to set a background about the defining attributes of new virtual training systems. Through the Avenor project we will focus on the instructional aspects of the technology and its importance in achieving a learning environment which challenges and supports effective training.

Introduction

Training has traditionally been considered in industry as a cost centered activity. It seems to be acquired that in short term, training consumes revenue. As main result, training is seen as the last response to some critical needs. While it is true that managers recognize that training is necessary to improve the human capital of an industry bringing employees to a level of proficiency that allows them to be more productive, the traditional concern keeping training at the absolute minimum remain prevalent.

In 1992, it has been estimated that American companies spent almost 30 billion per year on training (American Society for Training and Development, 1992). While this statistic could be impressive, it represents less then 1% of expenses on front-line workers. Moreover the traditional models of how educate and train does not reflect the evolution of the technology end emerging needs for different new kinds of skills.

Since then, an important reflection has emerged on new training models integrating new technologies and adopting more relevant design approaches. As a result of the introduction of advanced , computer-based training technologies compel companies, instructional designers, trainers and trainees to explore and adopt new learning models.

Much of the current research on learning and training in the context of formal training situations based their origins pointing out some depressing facts: employees, trainees, students in general are faced very often with a large amount of very complex skills, in sciences, mathematics, humanities. They can also successfully reproduce large amount of factual information on demand. They have enormous quantities of very precise knowledge. They can pass certifications, examinations successfully. But the main concern is that they are unable to show that they understand what they have learned. They are unable to build significant relationships among different kinds of information in order to apply and use them in an appropriate way depending on the context and specific needs. Interestingly, this problem is related on how and when a learner is acquiring new information to be transformed and integrated to become a new knowledge. Several studies stressed the importance of situated learning conditions while we are constructing new knowledge, letting the learner focus on real tasks in a problem solving situation.

Some studies already described this problem of "inert knowledge" which other researchers have further defined as knowledge that can usually be recalled when people are asked to do it, but it is not used spontaneously in a problem solving situation also if it relevant, because the way and conditions it has been learned (Cognition and Technology Group at Vanderbilt, 1990).

Interactive Multimedia as a technology in education seems to offer possibilities of allowing learners to participate in a more involving, meaningful and diversified learning situations, in which they can practice on real tasks and move from their status as a novice into the realm of an expert (Giardina and Brouillard, 1998).

In fact simulating a word in which the learner moves toward full participation, accessing the information according his specific needs, manipulating experiences and solving problems, should prove a powerful environment for understanding and also help with the transfer of concepts to new contexts.

Simulation training environments

As we already discussed, in contemporary theories of learning and instruction, learners are no longer considered as a person who merely reproduce knowledge or behavior that is presented to them by an instructional system, either instructor or technological environment, but more as active agent in his own learning process (Dede, C., 1995).This mind frame has led to new approaches to the design of instructional environments. One of these new approaches is scientific discovery learning or exploratory learning in which the learner is not given only direct instruction about the domain to be mastered, but he is invited to discover and apply the important concepts and relations in a domain by himself according with a given task (Jong., T. de, 1992).

The main assumption behind the exploratory learning approach is that knowledge discovered and refined by the learner will be based more precisely in the learner's attitude and knowledge configuration and have stronger links with learner's previous knowledge structures. The processes involved seem to be more intuitive and more qualitative in terms of relevant integration of new information in prior mental structures. In fact, the skills needed for the exploration itself are seen as important skills since they could help a person develop different strategies to deal with unfamiliar situations in more effective way.

These concerns have received a particular attention through the re-introduction of the Interactive training simulations as a powerful instructional device. As several studies already stressed, computerized simulations can fill in an important role as a training device for many reasons related as well to safety, economy, social reasons, as well to improve the possibility to access

BEST COPY AVAILABLE

invisible processes or let the learner to manipulate real phenomenon (de Jong and *al.*, 1992; Shute, 1993, 1997; Grimes and Wiley, 1990).

More important, is the fact that through the simulation approach we can focus on exploratory or discovery learning strategies since it represents a model of a real situation to be discovered by the learner.

Effectively computer simulations are quite popular in instruction, but there is no conclusive evidence of their effectiveness and efficiency. Some researches showing positive effects (Shute and Glaser, 1990; Faryniarz and Lockwood, 1992), and others stressing the failure to find significant advantages of simulations (Jong and de Vries, 1993).

Some possible reasons for the ineffectiveness of computer simulation approach is that learners for example, while interacting with a simulation encounter difficulties which they cannot overcome on their own. The lack of guidance or the adequate execution of exploratory processes, the lack of accuracy defining or analyzing a problem (Joolingen and de Jong, 1991), the switching between personal hypotheses and actions to be taken in the simulated environment, as well as all the concerns related with the regulatory processes and the learner modeling (Giardina and *al.*, 1997; Shute, 1996; Giardina and Brisebois, 1996; Zhang.and Norman 1994).

Other major concerns seem to be focused on the exactitude and completeness of the representation of the simulated domain as well as in terms of graphical representation (2D or 3D), and in the over-complexity or over-simplicity of the conceptual representation of the situation.

Several possible solutions for these problems seem to emerge, among them new directions focus on the design of three dimensional simulated worlds that can increase their complexity interacting with the learner and providing learners also with support to access the information in multiple ways in addition to pure simulation (Giardina and *al.*, 1997).

The Avenor Virtual Trainer try to bring new ideas of instructional model through the implementation of both dimension, the most appropriate graphical representation of a given task and the possibility to build a conceptual representation through diversified access modes to the information. The major focus of this paper is to deal with some of these typical problems concerning the design of instructional strategies for learning with computers simulations. We should remember that when a learner is interacting in an simulated environment, we need a new way of monitoring the interaction, because the initiative is shared between the learner initiative and the system response. The next following paragraphs will describe more precisely some of these concepts, and they will be followed by a section describing the solutions proposed in the Avenor Virtual Trainer.

Situated Learning in simulated environments.

There is a great interest in the ideas conveyed by the situated learning approach as drawn on several studies about the social dimensions of the learning process (Vygotsky, 1978). Effectively, situated learning could be defined as the activity in which knowledge is constructed and deployed is not separable from learning and cognition, but an integral part of what is learned. The learner build a significant meaning through his continuous participation and involvement in his own learning process using and understanding tools allowing him to simulate authentic activities. This concept is central to many other studies that defined the learning process in terms of a continuum in between a novice state of skills an knowledge to an expert state. The learner through his immersion and interaction in a simulated situation, gradually moves from a peripheral involvement (novice) to a deeper involvement and understanding. Several observations stressed already the fact that one of the key issue in learners motivation is the perception of their actions, the assessment requirements and the guidance on what and how they are learning (Giardina and *al.*, 1992).

One of the major issue for the learner is to have the possibility to refine his understanding, and his potential to become a more expert practitioners in a given domain, through the interaction with a responding and adaptive situation. Many dimensions seem to be related to this concern, and one of the emergent one is the possibility to use the landscape concept to develop useful options in learning in this kind of simulated environment.

Immersion is one of the new concepts, which already some studies on virtual reality pointed out (Dede, 1996; Giardina and Brouillard, 1997) as a major component for a deeper understanding of specific procedural skills. Immersion and its effects on the user is partly function of the engaging and realistic aspects of the learning experience by computers. It could be very simple or very complex depending on the completeness of the representation of the situation, from complete range of sensory experiences to much more simple combination of sound and pictures. It can be argued that training meaningfulness result mostly in the effective use of relevant instructional strategies then on the merely physical representation of a situation.

Many authors discussed the concept of immersion, stressing that there are at least two main aspects that should be considered in relationship with learner involvement : physical perception and cognitive perception. Effectively we spent a lot of energies on the physical aspects of possible interactions between a learner and a system, it is common to several virtual reality projects and it is strongly determined by the devices through which the user manipulate the environment .

Another direction is the design of particular systems , as Avenor Virtual Trainer, that can be given a set of attributes and defined rules about the task or activity represented where the learner can directly manipulate elements of the simulated environment , move around exploring this particular microworld and receive specific hints and feedback on the correctness of his actions. Another very important aspect of the immersion is the conceptual congruence between user's actions and their understanding of the knowledge embodied in the learning task. The importance of this concern is to make meaningful links between the decisions undertaken by the learner and the progress toward a possible solution. Early studies on simulation games clearly shown that the learner shouldn't achieve any significant progress only randomly selecting or making decisions completely on his own. We should be thinking in terms of giving him more simple to complex feedback, allowing him the possibility to select pre-established set of possible answers or some models of decisional path. More important within the interactive multimedia simulation the active involvement of the learner will lead to conceptual understanding directly about the situation in which he is working. This

BEST COPY AVAILABLE

is one of the major aspect that has been taken into account while designing Avenor Virtual Trainer (AVT). As we will see further , the AVT can allow different accesses to the same information, can provide several tools and diversified level feedback.

Fidelity of model representation

As we already stressed, in designing interactive simulation learning environments, one of the major concern is the domain model represented inside. Unlike in many traditional CBT learning environment , where the learner can only interact with some instructional design decisions carried by the system, within a simulation-based discovery system the model of the domain is represented, is executable and independent from the instructional strategy layer that could be added by the designer.

The interaction that results from this new kind of situations where learning complex skills relate to how the learner can move and manipulate objects efficiently in a three dimensional environments, has not been deeply explored. We argue that a novice that is attempting to process a large amount of knowledge trying to organize and integrate new information in his mental structure, he could be effectively involved if the domain model is realistic and allow him to operate as he was on the real situation. And this also if the simulation is implemented in a simple environment. By the nature of the interface and the three dimensionality of the interaction with this kind of context, learner cannot be passive, unlike in other learning situations that even implemented in a multimedia way present set of pre-established decisions in a very linear way. Effectively several study already expressed their doubts about a significant transfer of learning from a situation where the learner is not really stimulated to make decision on a realistic model to the real task.

Simulation models are designed to calculate the values of different variables from a given learner input. The potential of dynamic simulation is that a learner can manipulate these variables before or during on going interactions within the simulation seeing the results of his decisions. There is not a real problem, since the learner can focus on the single simulation and the system is only reactive to the learner actions and the procedural progression. A new challenge is when we want to add the instructional level as in a guided discovery environment (Dede, 1995, Dede and *al*., 1996), the learning environment needs to be aware of the state of the simulation, the progression of the learner and the state of the instructional events that could be dependant in a specific context. As the design of the interaction is mainly focused on a mixed-initiative between the system and the learner each of these state may be changing at every moment, by a learner decision or by an occurrence of a specific event in the simulation. The instructional events should be aware of these changing states and they should be able to change the kind of interaction and guidance during the learning process, intervening directly on the simulated model or giving hints to the learner.

Meaningful learning practice in a simulation environment: Avenor VT

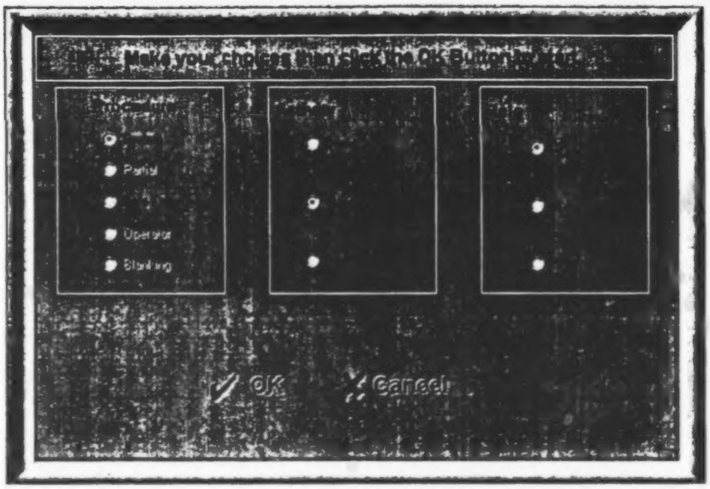
Several authors described crucial features related to way of thinking in a formal learning settings, focusing on the crucial aspects of situated learning and cognitive apprenticeship as powerful approaches to develop higher learning experiences. It has been argued that we should try to implement learning situations where we can observe, coach and practice to be effective. Where the novice-apprentice repeatedly observe a model mastering a given task or process, followed by an attempt of the learner to execute the task with a certain guidance (coaching) and ultimately reducing the participation of the system guidance (fading) as the novice can demonstrate the mastery of new skills. Furthermore, we should help the learners to articulate their knowledge, through reasoning or problem-solving process, enable the learners to reflect comparing their own problem solving process with those of an expert and finally but not less important, push the learners to explore more deeply in a problem solving mode on their own. We truly believe that we could rich a very meaningful learning experience through increased immersion, task realism, fidelity of representation and learner involvement Zhang and Norman, D.A., 1994).

Avenor Project Description

Interacting within the VT simulation

As we discussed previously, the learner at any moment can choose to interact in a different way and at different levels through the simulation. The main characteristic of Avenor VT, is that the learner can select to interact with different lockout procedures, from simple to more complex and he can learn, practice and refine these procedures playing different roles. He can switch from an *observer* learning strategy, watching *demonstrations* of TSL (Total System Lockout), PSL (Partial System Lockout), SEP (Safe Entry Procedure), and OL (Operator Lockout) Procedures, to a *practitioner* strategy through which he can *practice* performing TSL (Total System Lockout), PSL (Partial System Lockout), SEP (Safe Entry Procedure), and OL (Operator Lockout) Procedures.

For each Practice session, the learner can choose to play the role of the Operator (OP), the System Lockout Assistant (SLA), or the Person Performing Work (PPW). Naturally for each one of these different roles, the knowledge and skills to acquire and apply are different an complementary. The learner can analyze and define the task to be accomplished under different circumstances, in a different perspective and with several diversified constraints.



The feedback dimension during the interaction is very important, the learner depending the role and the procedure selected, receives contextual hints and feedback according to his actions and decisions. Object pop-up hints in the VR window are not provided during a Practice session to make things a little more challenging. However, the following feedback is provided:

1. Instructions are displayed in the *Status Bar* at the bottom of the screen. The learner can hide the instructions to simulate Practical Test conditions by clicking on the *Show Instruction* check box to remove the check mark.
2. A warning sound is played when the learner attempt to take an incorrect action.
   He cannot *fail* a Practice activity and his results are not recorded.

When the *Procedure* dialogue box will disappear the learner can start the practice activity.

When the practice starts, the *Play* button will change to a *Stop* button. At any time the learner can click on the *Stop* button to change the mode of interaction. Although, a practice activity cannot be paused, it must be completed from start to finish.

During a Practice session, the role the learner selected and the current role players will be displayed in the right-hand area of the screen. The selected role remains constant during the session, while the current role players will change as the situation changes.

For example, the picture shown below indicates that the learner has selected the Operator role and that the current role characters are the Operator and the System Lockout Assistant. In effect, this means that it is now time for learner (the Operator) to act because there is a match between the selected role player and one the current role players (figure 1).

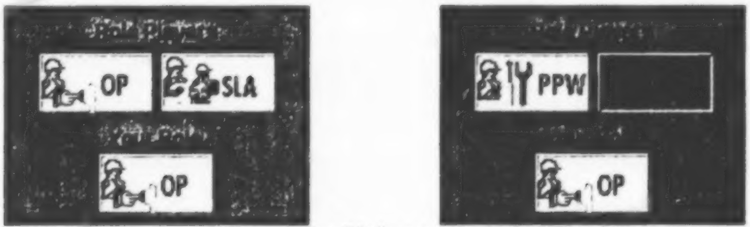


Figure 1: Possible learner roles in the VT environment

At times, the selected role player will not be one of the current role player(s). In these situations, the current role player(s) will act automatically and the learner will see a VR Movie of these actions.

For example, the picture shown below indicates that the learner has selected the Operator role and that there is only one current role player - the Person Performing Work. In effect, this means that it is not time for the learner (the Operator) to act because there is no match between the selected role player and one the current role players. Instead, a VT Movie will run which shows the Person Performing Work in action.

Other dimensions are also dispensable by VT when the learner immerse in the environment (fig.2). Some allows him to act as explorer, other as learner practicing some procedures or task.

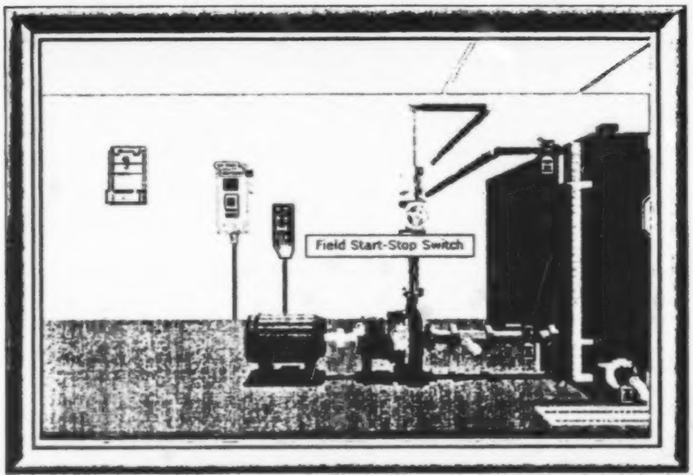
Figure 2: VT environment when the learner is practicing some specific task



Note here that the pop -up hint appears beside the object to facilitate the associative process. It is help the learner to become more selective activating discriminatory processes.
Table I resumes the principles dimensions available in the VT environment.

Table I: VT principles dimensions

VT Dimensions	*Learners possible actions*
Access mode	- *Logging-in*: create user-defined administrators, training supervisors and trainees. - *Explore mode*: the learner can browse around the 3D environment. He can select any of available - *Procedure mode*: the learner can watch demos of Lockout procedures. Ha can also practice them and test his skills with a Practical Test.
Exploration and practice	- *Looking around*: Its allows the learner to rotate his viewpoint to right or left. The learner has a complete control to explore the environments and he will receive only descriptive feedback. Its allows him to built a declarative understanding of the situation. - *Finding object*: by moving the mouse, the mouse pointer changes to a hand shape and identify the objects as one that the learner can get a definition and a quiz question for. It allows learner to be more selective activating discriminatory processes. - *Selecting object*: selecting an object, an image appears in the Current Object panel giving the learner Object Name Panel and a Definition panel appears in the lower-left area of the screen. - *Manipulating objects*: the mouse pointer changes to a fist when it is over object. This means that the learner can manipulate the object by clicking on. By zoom-out moving the learner has the possibility to see better significant details of a particular elements and refine his action or decision. - *Getting the tools*: during the interaction, when the learner is in Procedure mode, he can practice and test his skills in performing an Energy Control Procedure. A feedback will be given in order to guide him to select the right set of tools. - *Applying the tools*: the learner is asked to manipulate a specific object adjusting to the right position. The interaction lead the learner to activate several learning process, observing, moving around the object, selecting the right procedures to be applied and manipulating more in detail the tool elements.

BEST COPY AVAILABLE

Formative evaluation	- *Taking the pre-test*: if the learner log-in as a trainee, he should first take the Pre-Test in order to determine his current level of knowledge about Energy Control Procedures. - *Taking a formative* quiz: in explore mode, the learner can identify his knowledge about an object or a specific task. The learner can choose a specific context in which he want or hi is acting. The feedback provided help with several hints and suggestions for further actions or decisions. - *Taking a practical test*: At the end of a series of manipulations for a given task, the learner can take Practical Test. If he takes an incorrect action, an information is provided about the action he attempted to take and the correct action that was required.

The user has other generic tools that can use at any time during his/her interaction within the system. As:

- Keeping a Diary
- Training Supervisors.
- Checking a Trainee's progress
- Training Management

Validation Methodology and some Findings

We had a three phases validation process: functional validation, pre-validation and validation.

During the functional validation, we have asked 5 Instructional Designer to interact with Avenor VT and take notes on a pre-designed matrix (Giardina and *al.*, 1997.. The main objective of this step was to verify the functioning of the Virtual Trainer situation and all its functions.

Several points arise from this preliminary validation and they could be summarized as follow :

- the importance of the availability of mapping tool, helping the user to not getting lost within the content and the simulated environment.
- the necessity of different color codes for different kind of possible manipulations during the simulated activities .
- the importance to focuses more on the activation of selective perception (visual and audio), by the integration of specific visual and audio hints.
- the importance to diversify several feedback levels focusing on the general problem solving process and on the very contextual action that is occurring.
- the importance to maintain a consistent language level within the several possible categories of textual and audio messages (ex. definitions, guidelines, helps).
- the necessity to integrate spatial hints to decrease the lack of orientation.

After this functional validation several changes have been incorporated into the Avenor Vt.

During the second phase, the pre-validation, we have asked 5 practitioners (target population) to interact with the system for at least one hour. During the interaction we have observed the interaction process with an observation grid designed to collect some attitudinal aspects (ex. curious, interested, nervous, serious, amused, concentrated) as well as some external verbal behavior (ex. exclamation, comments, questions on technical or navigational aspects, on learning activity). A trace has been also recorded by the system, keeping trace of some activities results, wrong or good answer, etc.

At the end of the interaction session (60 to 90 minutes) we collect some students' impressions with a structured interview . The design of each question was directed by our predictions about how simulated environments and realistic tasks impact learning process. We coded the responses using the following framework :

- General topics
- Navigational and Interaction tools
- Potential learning actions by the learner
- Coaching strategies by the systems
- Similarities with real tasks
- Multimedia content representations
- Motivational aspects.

As a very global synthesis of the results:

- the learners find the environment very challenging and stimulating.
- the learners find that their engagement within learning activities was as well and reach as in the real environment, sometimes also better.
- they pointed out the multiplicity of content representation as one of the major factor, as well as the possibility of several manipulations during the activity.
- the learners consistently rated this experience to be most like real work, or real on the job training situation.
- they characterized positively the possibility to manipulate directly making errors, seeing immediately the consequences and having the possibility to refine their decision.
- the learners seemed to prefer an audio comment while they were manipulating an element.
- they justified the audio preference by an increased concentration on the task.
- the challenge and the complexity of the activities seemed to maintain the learners interest.
- the fact that all the students tried very hard to accomplish all the tasks solving the different problems presented to them, suggest that the learners were truly engaged in the activity.

- the learners stressed the importance of the very situated feedback they received, as a key factor to maintain and increase their confidence.
- our data suggested also that diversifying and increasing the realism and the complexity of the activity in a real engaging and meaningful process, can increase the student learning expectations.

After this pre-validation step, we reformulated some questions of the structured interview that were to much answer-inductive and we refined some question items based on some emerging unexpected points. (ex. redundancy between textual and audio messages, possibility to personalize several parameters during the learner interaction, ex. time., risk, etc.).

During the validation phase we asked 18 operators (target population) to interact with Avenor VT and we used the same revised collecting tools (observing grid, trace and structured interview) as in the pre-validating phase.

Analyzing, condensing and presenting the data, we observed several results :

- the users that have already a better understanding of the task they perform better during the simulation
- the users that have more refined mental model of the simulated environment they interact in a deeper way and they try more complex activities.
- the users that have no mental model of the simulated environment or task they get lost much easier and more frequently.
- the users' ability to refine or build such mental model depend on the time spent to interact with the system.
- the possibility to access multiple representation and manipulation of an activity seems to reduce considerably the time to build a more precise mental model of the task.
- the possibility to make errors during the activity, see the realistic consequences and have the possibility to readjust our decision seems to have a direct impact on the learning time.
- the possibility to choose different role to play during the interaction with the system, seems to bring a deeper understanding of the problems related to the real task.
- the majority of the users mentioned the importance of the feedback dimension and stressed the necessity to improve it, situating and diversifying more the messages.
- most users have employed the demo state of the system before the practice.
- the majority of the users seemed to use the formative quiz as a learning tool during the interaction, to self-assess the lack of understanding during interaction with the system.
- the interaction through a reactive simulated training environment seems to build a deeper confidence for the learner to solve complex situations.

Conclusion

Within the Avenor Virtual Trainer project, we tried to integrate the new potential of both the technology and learning strategies to improve the possible understanding during the learning process.

Of course we related in this article only a synthesis of some findings that we think could give some interesting directions of reflections .

Effectively the project has been designed to improve the access to an information simulated environment through several different tools and dimensions provided to the learner by:

- Elaborating accessible and useable tools to allow the learner to meaningfully interact within a multimedia representation of a situation.
- Providing an adaptive textual and audio feedback and coherent navigational and information metaphor which requires minimal explanation for the learner to understand and manipulate it.
- Supplying several problems and tasks to solve based on the information embedded in the simulation.
- Providing a formative evaluation dimension along the all learning process as well as a pre and post test evaluation to have some indications in terms of learning gain.

It seems to us that this study on Interactive Simulated Training Environments let emerge the importance of continuing the research and development on the pedagogical integration of new technology within the learning process. Already some concerns related to this experience seem to suggest that learning strategies such as exploration, simulation , problem solving, personalized feedback among others, if they are systematically designed and implemented in a realistic mediated situation can have an important impact on cognitive and affective dimensions of the learning process.

Abstract: The acceptance of animation technologies into our culture is growing within the up coming generations. Video games such as Sony PlayStation (SONY 2002) have become part of the culture for young people from kindergarten through undergraduate school. Animation technologies have been implemented into educational systems in the form of animated pedagogical agents (Johnson 2000). The research described here aims to take advantage of this wide spread acceptance of animation technologies by introducing animated pedagogical agents as teachers in an adaptive instruction environment called Adam.

Introduction

Gilbert (1999) discussed the implementation of an adaptive instruction system called Arthur. In this paper, Gilbert introduced the Many-to-One (M-1) instructional model. The M-1 instructional model refers to the relationship between educators and learners. In this model, there are many educators per learner. In order to fully understand this model, some terminology must be introduced. In this paper, courses are composed of many lessons. As an example, on a typical syllabus, there are many lessons listed that will be discussed through out the course. Lessons can be further divided into one or more concepts. Concepts are the smallest unit of instruction. These concepts are called instructional units through out this paper. An instructional unit has two subsections, instruction and assessment. In other words, each instructional unit has instruction, which is followed by an assessment for that instruction. Figure 1 gives an illustration of the M-1 instructional model.

In figure 1, there are three educators, Lopez, Brown and Smith, that teach the same course. This course has five instructional units. The rows represent a single course that is taught by the educator on the left. Therefore, figure 1 contains three implementations of the same course taught by three different educators. Each educator uses his or her own pedagogical methods to deliver instruction. The columns in figure 1 represent instructional units. Each instructional unit consists of instruction and an assessment created by the instructor at the top of the column. This implementation is how the M-1 instructional model begins. Another way to conceptualize the M-1 instructional model is to imagine a single learner in a classroom full of educators that teach the same subject, but each educators teaches the subject using a different pedagogical approach. In the physical implementation, the M-1 instructional model is not feasible. Using technology, such as the internet, it is possible to implement a representation of the M-1 instructional model. This implementation will be called Adam.

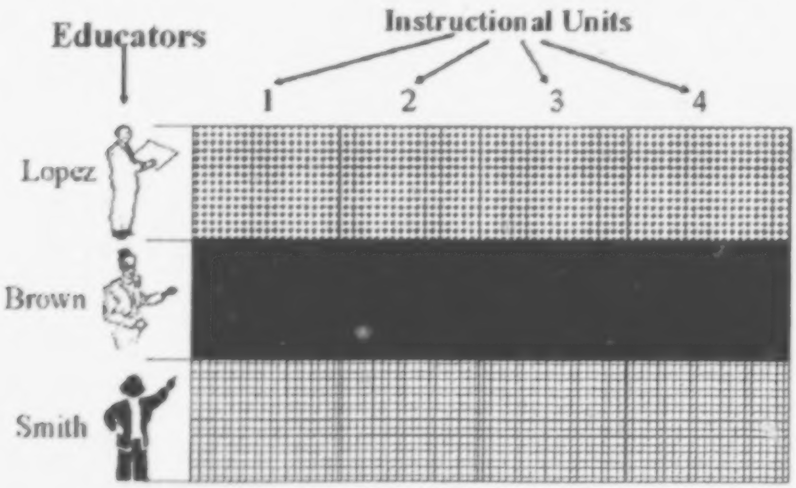

Figure 1: Many-to-One Instructional Model

Architecture

The physical architecture of the Adam environment begins with a web server and an instruction repository. This web server is the agent server. The agent server will host all of the instructional units that were described in the previous section. The instructional units are stored in an instruction repository. Each instructional unit is maintained as a web deliverable, instructional screenplay. The instructional screenplays will be discussed in further detail in the instruction creation section below. Instructional meta data such as the instructional unit's name, description, author's contact information, etc. will be stored in the repository for each instructional unit. This data comes alive when it is accessed by one of the delivery systems.

Delivery Systems

Delivery systems can exist on different web servers or they can reside on the agent server. Delivery systems select instructional units from the instruction repository. This process is called instruction method selection, which is discussed in further detail in the instruction delivery section. Recall that each instructional unit is composed of instruction and assessment. The instruction has been created by an educator using his or her own pedagogical style(s). When a learner uses Adam, the learner will be assigned an instructional unit from the instruction repository. The process of selecting an instructional unit, instruction method selection, occurs inside of the delivery systems. Figure 2 gives an illustration of how delivery systems interact with the agent server and the learners. Notice that there can be more than one delivery system.

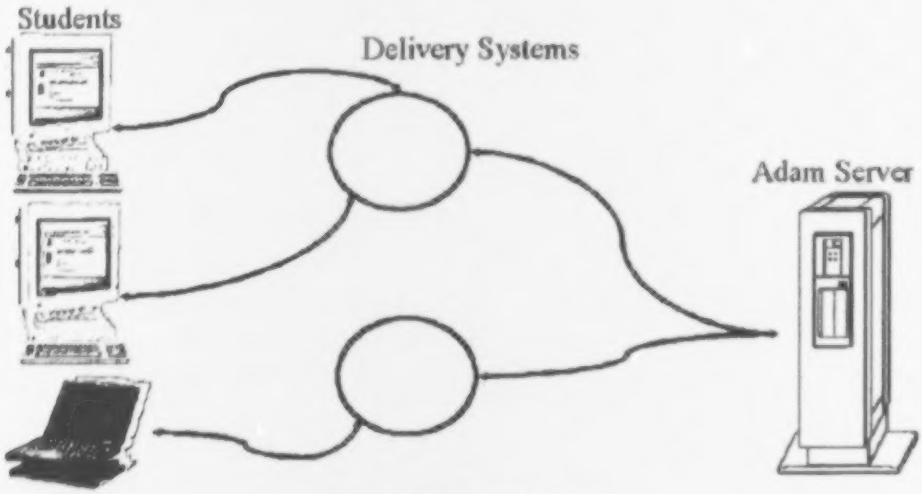

Figure 2: Adam Architecture

This is due to the fact that instruction method selection may vary. For example, in figure 1 the instructional units are numbered 1 through 4. The sequence for selecting these units may be 1, 2, 3 and 4 for a specific delivery system. For another delivery system, the sequence may be 2, 1, 3 and 4. This is an example of curriculum sequencing, which is the order in which instructional units are selected. Curriculum sequencing is just one variable that distinguishes delivery systems. The other variables will be discussed in the instruction delivery section. The server side of Adam has been discussed in this section and the user interface or client side follows.

User Interface

The user interface can be divided into two sections, navigation and content. Figure 3 has an illustration of the user interface layout. On the right hand side of the user interface there is a navigation frame. The navigation frame consists of a control panel and an animated pedagogical agent (Johnson 2000). The control panel allows the learner to start and stop a session, submit a question, logout, change the teacher's persona and to review previously seen instructional units. When the learner starts a session, the agent will begin to deliver instruction by speaking and manipulating web pages and/or objects in the content frame. The content frame is where all manipulatives used during instruction will appear. The agents used in this environment are implemented in the form of a web browser plug-in. This plug-in was developed by Haptek (2002). The

BEST COPY AVAILABLE

Haptek plug-in is downloadable and works on windows based machines. The plug-in performs text to speech in English and Spanish. It also provides voice manipulation and face animation. The face animation controls allow the developer to manipulate the agent's emotions in real time. The agent plays the role of educator in an elaborate educational screenplay.

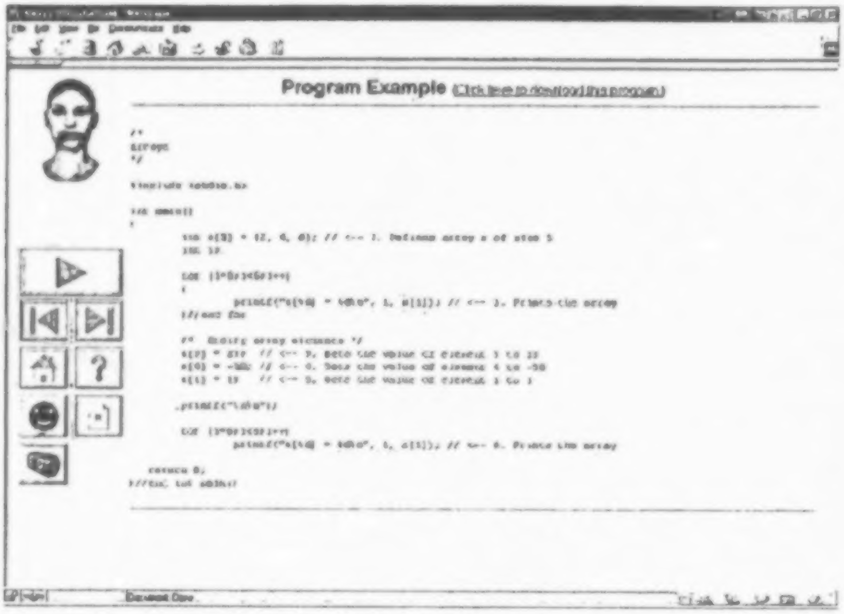

Figure 3: User Interface Layout

Instruction Creation

Before learners can use Adam, instruction must be created and implemented into Adam's architecture. The process of instruction creation is very tedious in its current state. The output of the instruction creation process is an educational screenplay that stars animated pedagogical agents. The process begins with real educators. In the current implementation, educators are video taped in a tutoring environment. The materials and all other manipulatives used during the tutoring session are collected when the session ends. Each session is focused on a specific concept. Recall, that concepts are later transformed into instructional units. The educators are also asked to create an assessment in the form of a quiz for each session. The goal of the assessment is to determine if the learner understood the concept(s). This process will be executed for a number of concepts with different educators. Once all of the concepts and assessments have been collected, the conceptual level of a Many-to-One instructional model can be implemented. In figure 1, there are three educators and four instructional units. Those instructional units would have been captured on video tape and the assessments created by each educator for those concepts will be collected as well. After all the concepts have been video taped from each educator and all the assessments have been collected, the instructional units will be created in the form of screenplays.

Creating Screenplays

The video tape of the tutoring sessions will be used to extract the educator's words as a digital audio file, .wav format. The .wav files of the educator's instruction will be transformed into compressed digital audio files that contain face animation information using Haptek's People Putty product. The output of this process is a .ogg file. In addition, each manipulative that the educators used will be transformed into a web deliverable format, i.e. html, video, Java, Flash. For example, everything that an educator writes or manipulates during the tutoring session will be transformed into a web compliant format. Next, the .ogg files and all the web deliverable materials will be placed along a conceptual timeline. This timeline is a reenactment of the tutoring session minus the physical presence of the educator and the learner. For example, an educator begins the tutoring session with a verbal introduction of a concept. This introduction may last 20 seconds. At that time, the educators writes a couple of sentences on a piece of paper or a chalk board. These actions would be replicated along

BEST COPY AVAILABLE

the conceptual timeline. Once the audio and materials have been conceptually synchronized, the educational screenplay will be stored in the instruction repository.

Storing Screenplays

The educational screenplays are stored in the instruction repository as instructional units. Recall, that instructional units are composed of instruction and assessment. From each tutoring session with a real educator, instruction is captured in the form of digital audio and web deliverable materials along a conceptual timeline. The assessments are also collected and converted into a web deliverable quiz. The instruction repository will house the digital audio/.ogg files, web deliverable materials and the conceptual ordering of the two together. The location or web address of the web deliverable materials is stored in the database on the agent server. This allows each web deliverable manipulative to be accessed via its web address, or url. This instruction creation process is very time consuming and labor intensive. In an effort to automate this process, an authoring tool is being developed.

Instruction Delivery

After the instructional units have been created and stored as screenplays with assessments, learners will be given access to them. When a learner uses Adam, the first task presented to the learner will be the educator selection screen. Figure 4 has a sample educator selection screen.

In figure 4, there are six different animated agents that can play the role of educator. Each agent has a different persona. Each agent has a unique persona that separates it from the others. Personas can differ in appearance and facial expression. Educator selection is similar to persona selection seen in popular video games such as Sony PlayStation (SONY 2002). In the video games, each player selects a team or person to represent him/her in the game. In Adam, the learner selects a teacher to provide instruction. The instruction behind the agent is stored on the agent server in the form of instructional units. Once the learner selects an agent educator, an instruction unit will be selected from the instruction repository.

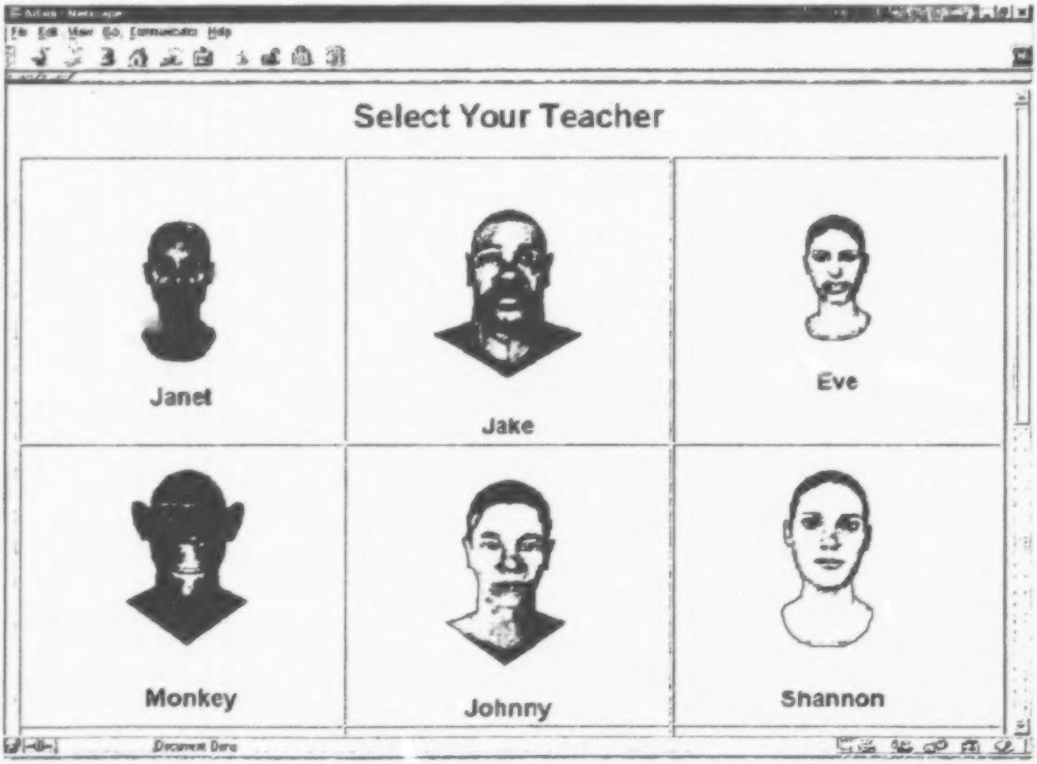

Figure 4: Educator Selection

BEST COPY AVAILABLE

Instruction Method Selection

The process of selecting an instructional unit from the instruction repository is called instruction method selection. Instruction method selection occurs at two distinct points within Adam, entry and after assessment. The first is the point of entry. When the learner selects an agent teacher, instruction method selection must occur. For example, learner Kristian logs into Adam. When Kristian enters Adam, a delivery system will be assigned to his course. Next, Kristian is presented with the educator selection screen in figure 4. He selects the first agent, Jake, along the bottom row to be his teacher. The system will refer to the instruction repository and select instructional unit number 1 from figure 1. Because Kristian is new to Adam, the first instructional unit will be selected at random. Notice that in figure 1, there are three different instructional unit number 1s. Assume Ms. Boykin's, the teacher in the middle, instructional unit 1 was selected. After the instructional unit has been selected, the interface will change and Kristian will be presented with the interface seen in figure 3 with Jake as the teacher. When Kristian presses the Play button on the control panel, Jake will begin to speak the transcribed text recorded from Ms. Boykin's tutoring session. The content in the right frame, figure 3, will change and display the web deliverable versions of Ms. Boykin's materials. This is the educational screenplay of instructional unit number 1 modeled after Ms. Boykin's tutoring session taught by Jake. Upon completion of instructional unit number 1, Kristian will be given the assessment created by Ms. Boykin for instructional unit number 1. After Kristian completes the assessment quiz, instruction method selection will occur again.

The completion of each instructional unit is marked by an assessment quiz. If the learner performs well on the assessment quiz, then the learner is presented with the next logical instructional unit using the same educator. For example, if Kristian performs well on the assessment quiz for instructional unit number 1, then he will be presented with instructional unit number 2, the next logical instructional unit, created by Ms. Boykin. In general, performing well is observed when the learner scores above a certain threshold. This threshold can be called the performance threshold. This may vary across delivery systems. For example, Gilbert [4] used a performance threshold of eighty percent for his studies. In other words, the learners had to score eighty percent or higher on their assessments before they could move onto the next logical instructional unit. Eighty percent was selected based upon mastery learning theory (Bloom 1976), where an eighty percent score determines mastery of a subject. Other delivery systems may set the performance threshold higher, i.e. ninety percent, or lower, i.e. seventy percent. In either case, the performance threshold must be met or exceeded before the learner can proceed onto the next logical instructional unit. If the learner scores below the performance threshold, then the learner will receive corrective instruction, which requires instruction method selection. Corrective instruction can be viewed as instruction that covers the same concept, but it is explained a different way. Therefore, the same subject is taught using a different instruction method. This process of providing corrective instruction when the learner falls below the performance threshold is called adaptive instruction.

Adaptive Instruction

Adaptive instruction refers to the process of adapting the instruction method in order to provide the learner with a personalized instructional experience. In some cases, adaptive instruction aims to accommodate learning style (Dunn 1978). In either case, adaptive instruction requires that an instruction method will be selected from a pool of varying instruction methods as seen in figure 1. Gilbert(2000) used a form of case-based reasoning to provide adaptive instruction in his studies. Each assessment quiz was defined as a case in those studies. All the cases consisted of similar attributes such as title, number of questions, number of questions answered correctly, etc. When a learner performed poorly on an assessment, the learner's assessment quiz would be transformed into a case. This case would be compared to previous learner cases. If a previous learner has performed in a similar manner as the current learner on the same assessment quiz, then the system would assign the current learner an instruction method based upon the previous learner's experience. This concept is based upon the premise that learners that perform similarly on the same assessments, may have similar learning styles. Therefore, establishing assessment quizzes as cases affords the ability to compare learners' assessments. For example, assume Kristian scored a seventy percent on the assessment quiz for instructional unit number 1 where the performance threshold was set to eighty percent. This quiz consisted of ten question and Kristian missed questions 5, 9 and 10. Also, assume a previous learner, Deborah, scored seventy percent on the same quiz, but she missed questions 5, 8 and 9. In the database, there is a case for Deborah and Kristian. Deborah's case contains information that shows she later passed instructional unit number 1 using Mr. Gabriel's instructional unit. Therefore, the system would assign Kristian Mr. Gabriel's instructional unit number 1 because Kristian and Deborah's assessment cases are closely matched and Mr. Gabriel's instructional unit number 1 worked well for Deborah. Adaptive instruction can occur throughout the learner's travel through Adam. An end result once the learner completes a course will be a learner map. The learner map represents all of the various instructional units selected by Adam. It is possible to compare learner maps at the end of the course in order to identify similarities between learners.

Conclusions

With the acceptance and integration of animation technologies into society, Adam has the opportunity to make a significant impact in providing universal access to alternative forms of instruction. As technology integrates further into the common household, tools such as Adam will give access to instruction from educators that would normally be out of reach. Adam has the ability to provide culturally responsive instruction to learners where their culture is not represented. For example, rural communities will be given access to instruction created by educators from across the globe. The demographic limitations of instruction are broken down by Adam.

Adam is part of an extensive research study that is supported by the National Science Foundation. Adam's instruction repository is currently being populated with instruction. The first prototype of Adam is being tested using introductory level computer science programming. On the instruction creation side, an authoring tool will be developed that will allow educators to create educational screenplays online. This tool is being called Eve. The tool will feature an animated pedagogical agent that plays the role of instructional designer. The agent will assists educators during the creation of their instructional units as screenplays. Educators will record their voice for instruction, which will be spoken during the screenplay. The educators will also have the ability to type in text that will be displayed on the screen and upload other web deliverable objects, i.e.: images. All of their materials will be stored on the agent server. The agent instructional designer will guide the educators through this process. It is estimated that Eve will be implemented within the next two years.

Abstract: We coined the term "mobile lessons" for lessons held outside of "artificial" environments as classrooms. During these lessons, all actors are mobile and must move to do the required tasks. Themes tackled in such lessons may be as varied as geography, history, ecology, dialects in linguistics... Mobile lessons are not a new teaching strategy, but new mobile devices may render it more efficient and more attractive. The aim is to place students in conditions germane to the ones in which experts work. We implemented in Java a software for creating and using mobile lessons and for monitoring students on the field. Contents and questions are in XML. Using this software, teachers of a high school in Sardinia (Italy) developed and experimented a mobile lesson on the archaeological site of Nora. Under the light of this experiment, a wireless, distributed and more sophisticated version of the software is under development.

Introduction

We coined the term "mobile lessons" for lessons held outside of a classroom, a science laboratory or any room situated inside the school. During such lessons, all actors are mobile and must move to perform the required tasks. Themes tackled in such lessons may be as varied as geophysics and mineralogy in geography, monuments in history, trees and ecosystems in biology, distance measuring in physics and geometry, or dialects in linguistics... Mobile lessons are not a new teaching technology or strategy, but new mobile devices may render them more efficient and more attractive. We believe that students better build their knowledge by going on the field, looking for information and by observing the real phenomenon. In other words students are put in conditions germane to the ones in which experts work. They feel more involved and must behave autonomously.

To integrate mobile devices in our constructivist "on the field" approach to learning, we designed and implemented a software we called `MobileLessons`. This software helps teachers to create lessons capitalizing on mobile devices. It also enables students to perform them on the field and finally provides tools to teachers to monitor students on the field in real-time. The implementation is in Java. Lesson contents and questions are specified in XML. The whole implementation relies on e-mate[1] (Giroux et al., 2001). E-mate is a framework for the delivery of mobile personalized geo-referenced services over many channels (PCs, personal digital assistants (PDAs), cellular phones…) and using multi-modality (text, image, sound…). The platform provides distributed services over the Internet. Most of them are accessible either from a computer, a personal digital assistant (PDA), or a cellular phone. A very interesting feature of e-mate is the generation on the fly of a usable interface for any device. Some services may be either written from scratch, or may result as a composition of others. Three scenarios are illustrating the possibilities of the e-mate platform. This paper focuses on the one we called "mobile lesson".

---

[1] E-mate stands for Multi-modal Architecture for Telematics Environment. The E-mate project began on January 2000 and must go on till July 2002. It is held at the Centre for Advanced Studies, Research and Development in Sardinia (CRS4) and is funded by the Italian Ministry of the Universities and Scientific Research.

The first release of `MobileLessons` was experimented in 2001. In the paper, we first describe the experiment of a mobile lesson, based on the exploration of a Roman archaeological site in Sardinia, Italy. In this experiment students used laptops connected to GPS. Then we present the concept of personalized course based on geo-referenced data, showing their preparation, their execution and their exploitation. Next we show how pedagogical strategies can be developed based on these lessons. Under the light of this experiment, a second release more powerful and more sophisticated of `Mobile Lessons` was developed. We present the second phase of the development of the mobile lesson infrastructure where students will use personal digital assistant connected to GPS system. In this second release, a mobile lesson is implemented as a set of distributed components called services, accessible through internet connection. We also describe briefly the system architecture which allows such services to be reached from different devices.

Experimentation

Using `MobileLessons`, teachers of a high school in Sardinia (Italy) developed and experimented a mobile lesson for the archaeological site of Nora[2]. This site is very interesting from an historical perspective because it contains both Punic and Roman ruins. The lesson was performed in June 2001 with a class of 12-13 years old students.

In the preparation of the lesson we followed two axis. The pedagogical axis addressed the lesson content itself, but also its prerequisites. In our case, some courses on the Roman civilization were necessary. These arguments were part of the pedagogical program of the class chosen for the mobile lesson. The software axis led us to build an application for both the edition of the lesson content and the management and monitoring of the students' work on the field.

While preparing the mobile lesson, teachers identified first zones of interest , then a set of hot spots for each zone (Figure 1). Hot spots correspond to precise location. Knowing the exact position of a student enables to ask precise questions on what she can see. So teachers first went to the chosen site with a GPS system and pointed out the coordinates of each hot spot. The objective was to bring students to discover these points once on the field. The information given by the GPS and associated with a position is a 2-tuple like East, 38° 59' 3,80'' ; North, 09° 00' 59,72''.

Each hot spot was then associated with other information. First a label like "the roman theatre" gives its name. Obviously, the students have to find a significant place, the theatre, and not a GPS position. But this is not enough, because the theatre is indeed a squared area whose side is more than forty meters long. The students must find the right position picked up by the teacher, near the theatre. Why the teacher chose this precise point is a question they have to answer. When some difficulties occur to find the right place, explanations, help and hints are supplied progressively. Their form may be as wide-ranging as the teacher's imagination can sustain: charade, riddle, description, etc.

Once on the field, teams of two or three students using laptops connected to a GPS system (United States Department of Defence, 1995) had to discover the significant hot spots previously identified by the teachers. They can wander wherever they want. Since the site is fenced, letting them free was not an issue. When students thought they were at the right location, the one identified by teachers, they asked the `MobileLesson` for confirmation. The current GPS position is then compared to the GPS position taken by the teacher. If the current GPS position is close enough, students have access to questions related to it. They may be general questions about the reached place but often they are questions about what the students can see from this precise location. Students have only to turn or move slightly to observe the place and discover or infer the right answers. A score was associated to each hotspot and each questions to motivate the students and to give them the feeling of a game. If the position was wrong, more information about the place is supplied. Receiving it, students have to move and ask again the software if they are at the right place or not.

---

[2] http://www.nora.it/.

We used latitude and longitude to represent a GPS position. For convenience, it might be possible to transform them into UTM coordinates (Carnes, 2002) expressed in meters using a specific algorithm but for our purpose, it was not necessary. We made many tests about the precision of GPS data and we accepted a position as right with an eight to ten meters uncertainty.

What Are Geo-Referenced Data?

Mobile lessons —and the other scenarios explored within e-mate— raised for us the question of what is a geo-referenced data and they should be modelled and implemented with repect to our purposes. Geo-referenced data are information associated to a location. Data and locations may be stored in various ways, for instance in geographic information systems (GIS), in relational or XML databases, but whatever the organisation is, it must be possible to find a location from data and conversely to find all data associated to a location. For our purposes, we distinguish two types of locations: "quantitative" and "qualitative".

A quantitative location corresponds a point on the earth. For that purpose, GIS are using various kind of coordinates, but numeric values are always required. That may be a global position system (GPS) location made of two data: longitude and latitude. Longitude and latitude are angles associated with a direction. For example, the roman theatre of the archaeological site of Nora situated in the Sardinia island is located at latitude East, 38° 59' 3,80'' and longitude North: 09° 00' 59,72''.

A qualitative location is associated to a place. The concept of place depends on the semantic context. The same word may represent different places in different contexts. It may represents a sector, a city, a region, a country or anything else. For example, "Cagliari" may stand for the city, the province of Sardinia, or the island of Italy. Locations are associated with properties or predicates. The nature of the predicate depends on the location type. We can say that two GPS positions are close or not according to a precision, that a position is situated to the south of another. We may say that a city is situated in a region or not, that a country contains a region. In this sense, data and location are basically and intrinsically associated.

It is often necessary to exploit geo-referenced data to give an appropriate response to a request. The answer true or false is never enough. For instance, for the request "I am in front of the town hall of the city of Cagliari and I would like to eat a pizza", an information system must answer by a list of restaurants where pizzas are supplied and which they are located in this quarter of the city. In itself, the answer does not contain explicit information associated to locations but geo-referenced information must be exploited to get a relevant answer. If locations are associated with predicates, it is possible to make inferences based upon mathematic or semantic criteria. Naturally, it becomes necessary to organise concepts and predicates and to make inferences on them, so an ontology (Gangemi et al., 2001) is often useful to describe the semantic context of application domains.

Axis of a Mobile Lesson

Not surprisingly, mobile lesson are developed and organized along three dimensions: pedagogy, contents and technology. The next sections will describe these axis.

Pedagogical Strategies

A mobile lesson is not an isolate lesson but an element of a pedagogical sequence. It is based on previous lessons and its outcomes have to be reused in successive ones. Part of the objectives is to integrate factors that help learners to build their knowledge in a constructivist way (Dalgarno, 1998). We believe that, when it is possible, going on the field, looking for information and above all observing the real phenomenon, therefore acting in a more personal and autonomous way, are fostering the effective construction of their knowledge by students.

Obviously, these factors have to be combined to other ones like adaptability or collaboration. More generally, it is important to understand some aspects of human expertise and teaching and how tutoring systems can exploit the expertise and teaching strategies (du Boulay & Luckin, 2001). Mobile personalised and geo-referenced systems (Giroux et al., 2001) seem to be a very appropriate mean to implement such expertises (Vérillon, 2000).

Preparing a mobile lesson, a teacher selects a zone and individuates there a set of hot spots. The objective is making the students discover these points when they are on the field. Each hot spot has an associated label. So, the students are knowing that they have to find a specific place. This label doesn't indicate a point but an area and the students have to find the right position picked up by the teacher (Figure 1). A set of advice under various forms must be supplied to help students to find the right place. They are proposed gradually after no succeeding tries. When near enough, students have still to test, whether there are at the right position. The student is then bring to rebuild the same reasoning process the teacher had.

Every step necessary for discovering the right point and the use of didactic transposition (Balacheff, 1994) helps students to remember and reuse knowledge in other contexts. Generally, on an archaeological site, documentation panels are describing interesting place with many details. In order to help students find some positions (maybe the first that students naturally think of), teachers may choose points near to these panels. For other hot spots, it is better not to do so because the interesting view on the place is elsewhere or because increasing the difficulty or yielding perplexity may give an extra motivation to students.

Once found an hot spot, students have to answer questions about the place they are. It is possible for a teacher to indirectly integrate the local documentation in the course of the lesson. Students have to observe all kind of details around them for giving good answers. Mixing general questions with observation questions leads students making deduction about the behaviour of people from antic civilisation, their scientific level, their art, etc. It is also an occasion to use more than one discipline and build links between them.

Obviously, an decisive mean to motivate students (Bunt & Conati, 2001) is by making the lesson like a game. Scores are associated to discovery of hotspots and answers to questions. The less attempts are made to find a hotspot, the higher the score is. When students observe that the software decreases the value of a right answer with respect to the number of wrong attempts, a group of students is encouraged to discuss and come to a general agreement before making a proposal.

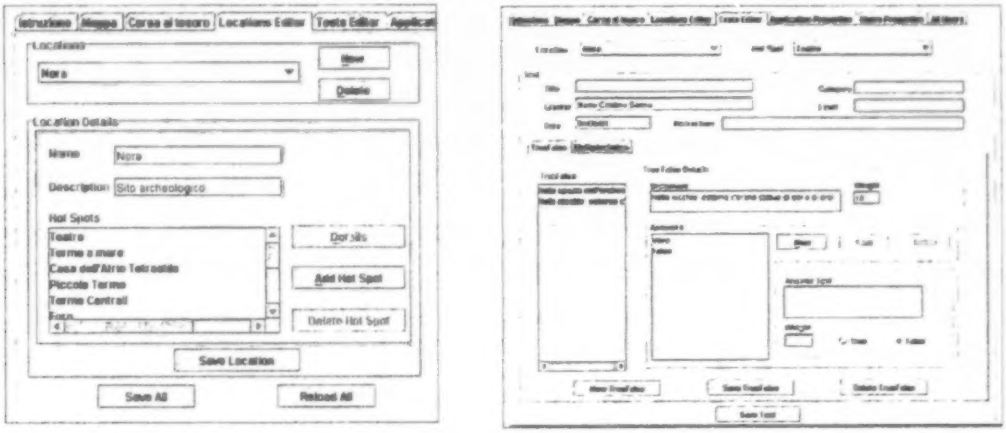
Lesson Organization

Content of a mobile is at the center of the four steps of the lifecycle of a mobile lesson: design, presentation, execution and exploitation.

First step: design of the lesson.

Obviously first teachers design the lesson and prepare the pedagogical material. A synopsis is made defining the theme and the objectives. A site is identified. Then teachers go on the site and identify important places and prepare location-based questions (Figure 2). They use `MobileLessons` running on a mobile computer (laptop, PDA, or mobile phone) equipped with a GPS system and connected to Internet if necessary. Finally, teachers prepare help and hint that students might receive and complete lesson description. During this step, documentation is built and referenced and a scenario that describes the tasks to complete is elaborated.



Locations: Nora

Name: Nora

Description: Sito archeologico

Hot Spots:
Teatro
Terme a mare
Casa dell'Atrio Tetrastilo
Piccole Terme
Terme Centrali
Foro

Figure 2 Hotspot editor and questions editor.

Second step: presentation of the lesson.

Once the lesson is ready, teachers present it to the class. They show the map of the site, present the tasks to do, and show also how to manipulate the devices and software. They also have to build the students' groups. The lesson is made in teams of two or three students.

Third step: lesson execution.

Then students go on the field under the responsibility of teachers. They have to follow the lesson scenario and find the places pointed out by teachers (Figure 3). They may have to find them following a precise order (different for each group) or not. Depending on the lesson theme, they have to observe monuments or site details, take notes, find minerals or vegetal, answer to questions using the help of documentation, take photo, etc. They may also have to measure things on the field as if they were scientists in a real context. If software allows it, teachers can follow the path of every group on the site map (Pfoser & Jensen, 2001). It is possible to track them if every computer sends regularly its position to a remote service.

BEST COPY AVAILABLE

Fourth step: course exploitation.

The class analyses data picked up on the field and reports can be done. Teachers may add also every kind of explanations and give general synthesis.

Technology

For the experimentation describes in this document, we prepared an autonomous software for supporting the lesson. We built an unique application installed locally on each laptop used by students. Lesson data were also stored on computer. The main problem for students is to move on a sunny site with a device which is a bit heavy, that requires many precautions and upon which it may be difficult to read due to the sun. Nevertheless, this experimentation was absolutely necessary for testing all elements of the lesson.

Encouraged by this success we designed the mobile lesson as a scenario of the e-MATE project. It uses the general infrastructure we built to deliver on-line services. Software and devices used on the field are completely different but the content itself of the lesson remains the same. We also integrated results of the experimentation and comments of all actors involved in the process to improved the way of presenting data and we added modules not implemented previously. Students on the area of the lesson, are now using a PDA. Only a part of software is installed on it and assures all connections with the school web site and the remote part. The PDA is equipped with a GPS system that automatically gives its position coordinates. This position is transferred to the remote architecture and so the service can detect if a student is facing an hot spot of the lesson or not.

We can define the mobile lesson e-learning service as a distributed software application, that delivers an adapted geo-referenced information on request. Figure 4 gives the architecture of the system that support the mobile lesson. Only a part of the service is loaded on it, the terminal tier. As several PDA

BEST COPY AVAILABLE

are simultaneously connected an HTTP server is required to manage for each device the remote tier of the service. It find its resources in the application server that deployed it. The HTTP server itself finds the remote tier of services required by the users in the service portal where the application server has published them after their deployment. Data exchanged (Zhang, 2000) between PDA devices and the HTTP server is contained in an XML document (XML, 2000).

E-mate architecture is a software architecture aimed to support the development of Mobile Personalised Location based Services (MPLS). It defines a model of services and provides a framework that facilitates the deployment of new position-aware services available through multiple channels. Distributed systems supply for a conceptual framework for building efficient and secure distributed services (Coulouris et al., 2001). E-mate addresses both the heterogeneous nature of access and the management of user sessions.

The architecture contains three main elements: The application server, the service portal and the service viewer. The application server deploys new services and publish them into the service portal. Deploying new services means launching the server session of a service. It is a part of a service which runs on the same workstation that the application server and even if no users are connected to the service. The application server also publishes services. It consists in storing a piece of each service into the service portal, the part that moves dynamically to any client that requires the service (the remote tier in the above example).

The service viewer is the user entry point in the system. For personal computer, it is an autonomous application that runs on it. For PDA, it is composed of two parts, due to the fact that they cannot dynamically load code: a local one and a remote one. After the user identification, it looks for the services published on the service portal. Then the user chooses the service with which working.

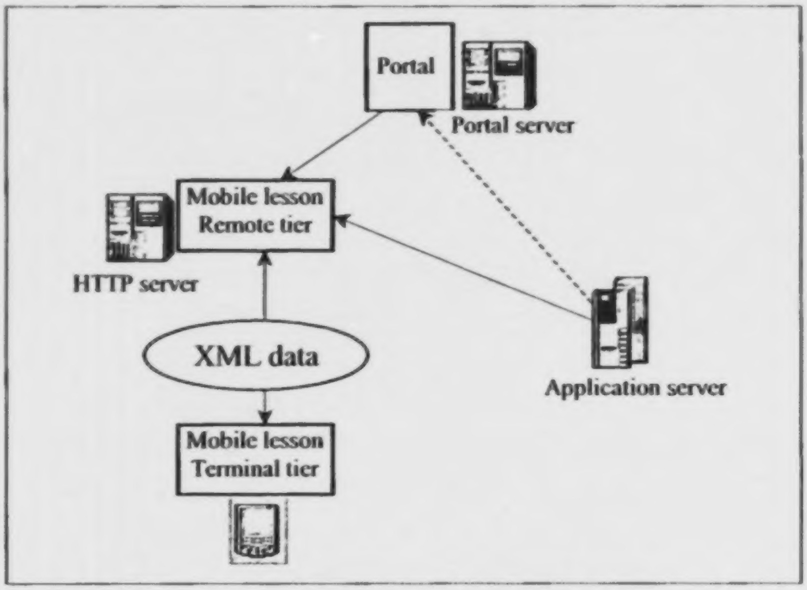

Figure 4 Communication in the case of distributed architecture.

Conclusion

A mobile lesson is the combination of three complementary axis: pedagogy, content and technology. Teachers are in charge of the preparation of the lesson itself and its contents, and computer scientists are responsible for the preparation of software to support the lesson on the field. Our experimentation proved the feasibility and the interest of mobile lessons. The involvement of teachers in the preparation of the lesson and pedagogical documents was critical and we are very grateful to them. The application we built for editing documents and for the execution of the lesson itself, was robust enough to avoid any problem on the field. The satisfaction of everyone and the desire of going more deeply in the experience tell us that it was a success. Besides its first objectives, a mobile lesson such as the one we described in this paper lead students to develop their own learning strategies. As our main conclusion, we can claim that associating various types of information, proving, succeeding, failing and trying to understand why, in a playful and motivating way, are surely among the best ways to acquire knowledge.

Acknowledgement

This project would not have been possible without the full support and participation of the Scuola Media Statale no 2, Assemini, Italy. In particular, the collaboration of the teachers Mrs Maria-Cristina Sanna and Mrs Giovanna Arru was invaluable. They were so generous of their time, their experience and their enthusiasm. All our thanks also to the students who participated to the lessons at Nora. Finally the Preside Mr. Pier Enrico Carta made everything needed to bring this project to reality in his school.

The VITAL Project
(Virtual Instructional Training for the Advancement of Literacy)

http://www.mun.ca/educ/vital/index.html

Dr. Marc S. Glassman
Professor
Faculty of Education
Memorial University of Newfoundland
glassman@mun.ca

Abstract

The **VITAL Project (Virtual Instructional Training for the Advancement of Literacy)** is a multi-faceted, dynamic and evolving web-based professional development (PD) project. The central focus of this project is the provision of current and relevant information and knowledge in literacy education to primary grade teachers, along with the inclusion of an interactive forum among these teachers. As an asynchronous knowledge-support and mentoring PD program, the VITAL Project provides a complimentary "tool" for teachers in their attempts to help students attain the "expected outcomes" as outlined in the English Language Arts Curriculum for the Province of Newfoundland and Labrador.

OVERVIEW

The Province of Newfoundland and Labrador is currently at a crossroads as far as its educational system is concerned. A unique situation confronts the Department of Education, a majority of the 11 provincial school boards, and teachers throughout the province. With approximately 66% of the public schools being classified as "rural", the resources and logistics necessary for providing continuous, relevant and up-to-date professional development (PD) to all teachers in this province is, at best, a challenging but necessary task. However, the uniqueness of the situation stems from the fact that schools throughout Newfoundland and Labrador are, for the most part, "wired" for Internet access. Thus, while it may appear to be a daunting task to provide needed PD to teachers throughout a Canadian province that is three times the size of the state of California, there is a sense of potential in every challenge. The task of providing professional development in the area of literacy education might be accomplished, in part, with the creation of an in-service program delivered on-line to any teacher in the province, regardless of locale, on an "as needed/where needed" basis. Factors such as school closures for "PD days", or attempting to secure substitute teachers to replace regular classroom teachers so that these regular classroom teachers might avail themselves of needed professional development, are, in part, eliminated with the provision of asynchronous and synchronous computer-mediated on-line training. One undertaking in the provision of professional development in the area of literacy is the VITAL Project (http://www.mun.ca/educ/vital/index.html).

THEORETICAL RATIONALE

The concept of "telementoring", in a virtual sense, is not new. Wighton (1993) discussed the potential benefits of this form of professional development with the creation of an "educational network" of teacher mentors in the Canadian province of British Columbia. He envisioned a network where "...a cadre of experienced telecomputing teachers would be recruited to provide educational support" for other teachers within the province. He envisioned an on-line network with mentors being proactive in the identification of novice teachers, as well as being reactive with the on-line support they supply to the questions posed by their "mentees". "The support would be primarily pedagogical in nature, focusing upon helping teachers to use telecomputing activities within the curriculum".

Wright (1996) posed an interesting position regarding the "adjustments" that teachers needed to make in the use of technology. His position provided a needed note of caution in the creation of this form of "high technology" instruction. Wright contended that just as certain teachers had to undergo a "paradigm shift" in their implementation of computer technology within the curriculum, others had to "...adjust their paradigm to accept non-technology oriented users." There needed to be a sort of balance and accommodation between the needs and abilities of "technology-oriented teachers" and "non technology-oriented teachers".

McKenzie (1997) also raises a note of caution for those who utilize technology within the confines of "knowledge industries"(i.e., universities, colleges and public schools). He contends that a "shift" is needed away from the notion of "imparting information" to a "focus upon learning". This "shift" must take into account the background knowledge and experiences of the learners, be they students or the teachers of these students. As well, the learning necessary to undertake this new form of education will come from various resources in a variety of formats. Thus, a "dramatic shift" in the basic focus and specific purposes of education and learning might be undertaken utilizing the technological benefits of computer-mediated instruction and learning. "Sources will no longer be static and fixed. They will be dynamic, open and available."

The proliferation of computers in primary grade classrooms has also created a shift in how reading and writing are both taught and learned. Labbo, Reinking, and McKenna (1998) asserted that the use of computer technology would cause dramatic changes for both students and teachers. Primary grade students would have greater access to computers, which was once reserved for students in the secondary schools. As well, the preparation of teachers would need to change to help pre-service teachers understand the role that computer technology might play in the classroom of today. For the in-service teacher, staff development needed to focus on the needs of teachers who had various levels of expertise and competence with the use of computers in a literacy classroom.

In 1998, within a report submitted to SchoolNet / Rescol by TeleLearning Network Inc., a major review on the effective uses of online electronic resources and tools in the classroom was undertaken by Bracewell, Breuleux, Laferrière, Benoit and Abdous (1998). They sought to document the emerging contribution of on-line resources and tools to classroom learning and teaching. Of the many trends that they documented, two were of significance for the theoretical rationale underlying the VITAL Project. One of these trends was the "...emergence of a new mixed mode of learning: face-to-face and online learning activities." They viewed this trend as significant in that the role of the teacher was changing from one of "transmitter" to that of being a "facilitator". Learners went from a situation of "low access" to the utilization of technology in the classroom context to one of "high access", where this form of technology became at intricate aspect of their total academic context. A second trend viewed by Bracewell, et al, was that access to information was becoming "...more direct, interactive and flexible". Curriculum content went from being pre-organized, with a scope and sequence of codified curriculum-centered objectives, to a learner-centered curriculum, constructed to meet the needs and abilities of students. Free access to on-line materials was supported by the teachers as a means of helping students attain a sense of ownership of certain aspects of their own learning.

Bruce (1999) states that many academics have defined schooling as "...the activity that occurs within a certain space, the classroom, and a certain time, the school day." However, he contends that this notion of traditional education is changing as we see the shift in the "center of learning" from a fixed "bricks and mortar" site to one in a virtual context. "The concept of learning freed from the constraints of time and space is thus curiously reduced to learning confined within a new frame of asynchronous communication." He urges professional educators to become knowledgeable in this form of asynchronous instruction and learning, so as to maintain the role of proactive facilitator to this changing paradigm, rather than being a mere reactor to the changing times.

Educational improvements, according to Cooley (2001), need to come about through "...planned, coordinated and ongoing staff development", focusing upon the enhancement of a teacher's instructional "skills" and methodologies. He proposes a staff development model based on the concept of utilizing "teachers as trainers". His four-phase model on the procedures and pedagogy necessary to implement this form of staff development is well documented in a theoretical and practical manner. "When systematically implemented, these steps provide a powerful grounding for educational change."

Carlson (2001) sees the need for renewed "educational partnerships" to help build "...a systemic infrastructure to provide access for all teachers." From her contention that "collaborations empower individuals", she proposed that there is a need to "re-invest in human potential" through experiences aimed at teacher training and pedagogical renewal in the area of the skills and uses of technology. It is her belief that all those interested in education need to encourage "those willing to innovate" in the development and delivery of "grassroots initiatives" to help make this collaboration, training and renewal possible.

The VITAL Project is an example of this form of grassroots initiative.

PROJECT HISTORY

As a professor in the Faculty of Education (http://www.mun.ca/educ/) at Memorial University of Newfoundland (MUN), the project coordinator had the opportunity to develop and implement seven web-based courses in the area of literacy education. Since the winter semester of 1997 until the fall semester of 2002, these two graduate and five undergraduate courses have been offered a total of 30 times to 535 university students. Students from Canada have come from every province other than Quebec, as well as two of our three territories. In addition, students have attended these classes, in a virtual sense, from three countries outside of Canada (e.g., the United States, England and Venezuela). However, not every student taking these courses was enrolled in either an undergraduate or graduate program at MUN. As of this semester (i.e., Fall of 2002), 39 of these non-program students took one or more of these MUN web-courses and transferred the credit to their home university towards an degree program in education, or for certification credit with a particular provincial or state department of education. Interestingly, 13 teachers across Canada took various web courses on-line for university credit, although they already had a Master's degree in education. Their rationale for taking certain of the literacy web courses was for professional development. This serendipitous experience gave rise to the idea of attempting to create an online professional development web site to bring needed PD in the area of literacy to teachers in the province of Newfoundland and Labrador.

A proposal was by the project coordinator to the Newfoundland and Labrador Teacher's Association (NLTA) for a Centennial Fund grant of $5000. This money was to be utilized for hiring a web designer to help bring the web site on line. As the coordinator and main writer on this project came from a university environment, it was important to include literacy specialists from within the school system. The decision was made to focus the prototype for the VITAL Project in two of the 11 school districts within the province of Newfoundland and Labrador. The coordinator then approached the literacy specialist in the Avalon West School Board and the primary/literacy program coordinator for the Vista School Board. Together, this team concluded that an ideal target group for this project would be the K-3 primary grade teachers in the two aforementioned school boards, especially given the reality that our province was in the process of implementing new curricula in the area of primary literacy. Also, both of these boards were geographically large, with a majority of their primary/elementary grade schools located in rural locations. These locales are difficult to access by road in the winter months, but would pose no problems for the delivery of a virtual PD program in the area of literacy.

Carpe Diem

Phase One of the VITAL Project, currently online at http://www.mun.ca/educ/vital/, was the writing of the basic structure of the web site, which consisted of literacy theories, innovative and practical instructional strategies, and the inclusion of hyperlinks to various web sites pertaining to primary grade literacy. The winter of 2002 was the period designated for this creation and initial implementation.

Phase Two of this project will involve the primary grade teachers in the two aforementioned school boards viewing the web site in an asynchronous non-linear manner, and providing specific feedback and comments to the project team. An on-line questionnaire will be created to help facilitate this interaction. Specific topics pertaining to literacy theory and/or pedagogy that are requested by any of the participating teachers shall be created by one of the project team members and included in the next phase of the project. As well, specific school board centered PD topics will be created by each of the two literacy/primary specialists and included in the web site. This will enable these specialists to conduct certain aspects of PD in their districts in a virtual manner. The fall term of 2002 is the period designated for this phase of the project.

Phase Three of this project, to begin in the winter of 2003, will involve the implementation of the requested additions to the initial web site, as well as an interactive forum. The SiteScape Forum or Web CT will be utilized to undertake this form of asynchronous interactions between the members of the project team and the participating teachers. As well, asynchronous interactions will be facilitated for on-line discussions among the participating teachers.

SUMMARY

With the onset of curricular changes in the area of literacy, professional development of in-service teachers has been a component of the continuing education of all educators for the past 30 years. The conceptual framework that serves as a virtual "scaffold" for this project is created with an integration of self-perceived professional needs and an on-going interaction between and educated learner and mentors. The "virtual" aspect of this project is contained within the asynchronous on-line experience in which teachers may partake. The "instructional" component is both indirect and self-paced, with interactions not only between the web-facilitators (i.e., mentors) and the participating teachers, but also among teacher across the province. The "training" component is on a "when needed/where needed" basis, and is determined by each teacher upon their own personal reflections of their individual needs and abilities. The "advancement" comes about with the provision of professional development on a continuous basis in the crucial curricular area of expressive and receptive language across the curriculum. From the experience of actively participating in each phase of this project, individual teachers may enable themselves to effectively and realistically affect professional change.

Using the Web to Teach Democracy

Ilia Goldfarb, Creative Director/Web Developer
The Spirit of Democracy Project, Faculty of Education
University of New Brunswick, Canada
goldi@unb.ca

Abstract: The Spirit of Democracy Project was initiated in 2000 by the University of New Brunswick, Canada, Faculty of Education in partnership with the Russian Association for Civic Education, and was made possible through financial contribution from the Canadian International Development Agency. The focus of the Project is the development of online citizenship education curriculum resources for use by teachers in Russia and Canada. The Canadian and Russian project teams are developing materials for similar topics based on local content. Researchers, on both sides, create learning opportunities using situations and springboards. The situations present democratic issues and concepts, for example the value of loyalty, or the meaning of privacy. An important role in the Project is assigned to visual materials and creative use of hypermedia. The Project led to close collaboration between Russian and Canadian social sciences researchers, teachers and students.

Introduction

The Spirit of Democracy Project began in the summer of 2000. The project was initiated by the University of New Brunswick, Canada, Faculty of Education, Citizenship Education Research and Development Group, in partnership with the Russian Association for Civic Education and Uchitelskaya Gazeta, and was made possible through financial contribution from the Canadian International Development Agency.

The organizing idea for this project was born several years ago during a meeting of two Canadian researchers, Andrew Hughes and Alan Sears in a discussion with colleagues from Argentina on the topic of helping to foster the emerging democratic culture in that country. The Argentinean colleagues said: "Don't teach us the structures of democracy, we know all about the structures of democracy; teach us the spirit of democracy" (The Spirit of Democracy 2002a). In the summer of 2000 Russian and Canadian teams for the Spirit of Democracy project met for the first time in Canada to discuss how they are going to teach "the spirit of democracy".

The goal of this project is to help Russian educators to develop a new dynamic approach to citizenship education in public schools. The main focus of the Project, from the beginning, was on the development of online curriculum resources on the "spirit of democracy" for use by teachers in Russia and Canada. The approaches used to convey "the spirit of democracy" include blended learning, situated learning, and creative use of Web media to effectively teach democracy on the Web. A lot of effort has been put into making the Project site a truly democratic learning environment, including links to national and international democratic sources.

Nurturing the Spirit of Democracy

Web-Based Situated Learning Approach

The Spirit of Democracy project is using the Web to deliver online resources: content, instructions, along with a discussion environment for teachers and students. These curriculum resources can be used as a complete set of materials or as individual lesson topics for different subjects such as Social Studies, History, Citizenship Education, etc. The Canadian and Russian project teams are developing project materials for similar topics based on local content. As a result, the information presented on the Canadian site is relevant to the lives of young Canadians, and the content on the Russian site may differ and is relevant to the lives of Russian students.

Web media by its nature is the most democratic type of media and is ideally suited for conveying the "spirit of democracy " idea. Web-based studies immerse students in an online learning environment that allows them to access all original materials, even those provided for teachers. The Web also serves as a unique source of "live" information. By providing hypertext links to government organizations, international organizations, educational Web sites, and online magazines, The Spirit of Democracy learning materials are always up-to date and offer information on recent important developments in the area of Citizenship and Social Studies in Canada, Russia and all over the world. In this paper the author is using the Web media definition from Huss (1999), where the Web media is defined as the use of the text, images, animations, sounds and video on the Web, supported by Hypertext Markup Language (HTML).

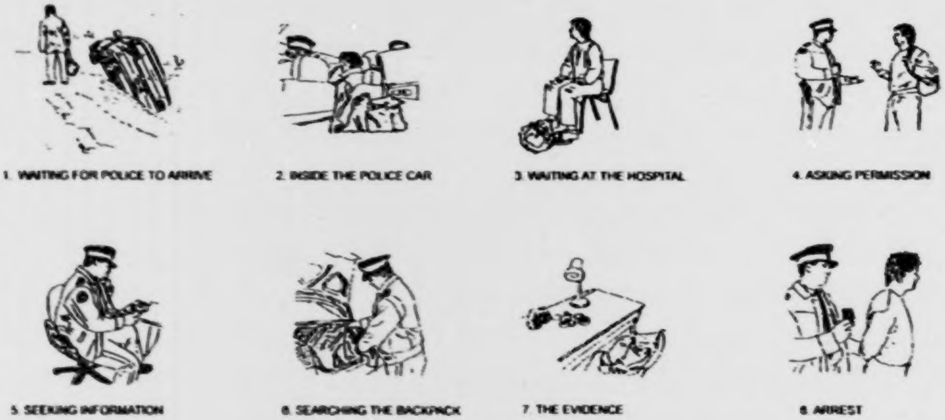
Combined with the creative use of multimedia and hypermedia Web based learning offers unique opportunities for educators. The Spirit of Democracy Project's learning approach is based on the ideas of Lev Semenovich Vygotsky who is widely known as "The Mozart of Psychology". Vygotsky, along with Piaget and Bruner developed the foundation for the concepts of Situated Learning and Anchored Instruction (The Spirit of Democracy 2002b). The Situated Learning approach is based on Situated Cognition Theory that suggests that learning is tied to authentic activity, context and culture (Brown et al. 1989). "An authentic context for citizenship learning must be a situation in which "real" citizens might be required to think and to act. It can be current, historical, or both; it can be near or far in both time and place" (Hughes et al. 2000). The Spirit of Democracy Project provides teachers and students with a wide range of "real life" situations. The Project is using a "blended learning" approach in which teachers use online materials in combination with conventional classroom training.

Use of visuals and Web media

Within The Spirit of Democracy Project, developers, on both sides, create learning opportunities using situations and springboards (anchors). The situations present democratic issues and concepts, for example the value of loyalty, or the meaning of privacy. The uniqueness of the approach taken by the Spirit of Democracy project is that researchers use authentic materials to involve students in learning and discovery. A very important role is assigned to visual materials. The situation is usually presented to students by showing a sequence of 8-10 pictures. The pictures should be descriptive enough to tell the story and appealing enough to draw the students in to a discussion about a particular topic. To achieve these results, the project illustrator has to work closely with researchers to portray the situations they want to use.

The topic of "Privacy" is a good example of such joint work between a researcher and an illustrator. One of the scenarios dealing with the topic of "Legal Aspects of Privacy" involves a discussion on the case of unreasonable search and seizure (Mr. Bagnell's case). In the learning activity "You Be the Judge" students need to learn all the details of the case and make a legal judgment (The Spirit of Democracy 2002c). The factual materials of the case are presented as a series of illustrations that lead students through the sequence of events of the actual case (Figure 1). One of the important conditions of this activity is to create a simulation of the court environment and help students experience the process of rendering a fair judgment. The use of visuals here is much more appropriate than the use of newspaper or magazine articles. Such articles usually contain judgmental opinions that may influence students' decisions one way or another. The researcher needed to spend a considerable amount of time working with the illustrator on the details of each scene, making sure that it properly presents all the facts of the case without any additional visual information that might influence students' opinion.

Along with the visual story presented through illustrations, the hypertext links allow students to learn the facts of the case and get additional supportive information, such as, excerpts from the Canadian Charter of Rights and Freedoms, the Controlled drugs and Substances Act, excerpts from precedents that deal with search and seizure cases and from the Privacy Act of New Brunswick, and a discussion of reasonable grounds. It is interesting to mention that our Russian colleagues are having a difficult time translating the word "privacy" as there is no equivalent in the Russian language. Currently in Russia people are using the English word "privacy" to convey the correct meaning of the concept. The idea of having a Privacy Commissioner is also something unheard of in Russian society.



1. WAITING FOR POLICE TO ARRIVE

2. INSIDE THE POLICE CAR

3. WAITING AT THE HOSPITAL

4. ASKING PERMISSION

5. SEEKING INFORMATION

6. SEARCHING THE BACKPACK

7. THE EVIDENCE

8. ARREST

Figure 1: Mr. Bagnell's case

Another set of illustrations was created for the "Images of Chile" springboard that is used to initiate students' discussion about "due process" and, in particular, human rights violations as one of the most important aspects of this concept (Figure 2). Working closely with a researcher, an illustrator portrays the story of a person missing after a confrontation with Chilean police. The visual story is supported by several hyperlinks to the Amnesty International Web site with articles about human rights violations in different countries such as Cuba, Guatemala, Bosnia and to the UN's Commission on Human Rights Web site.

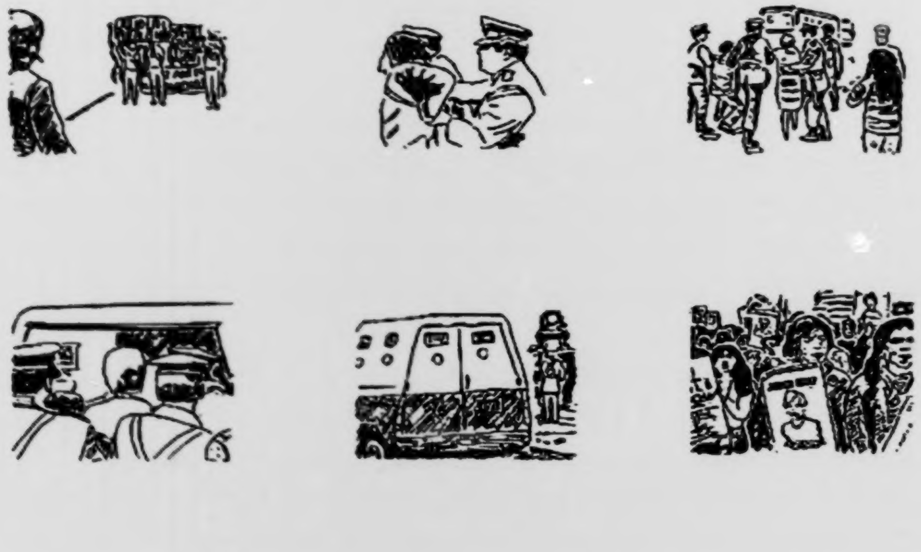


Figure 2: Images of Chile

BEST COPY AVAILABLE

Students are presented with images and asked to discuss what fundamental rights have been violated, how the due process of law could be properly applied in this situation, and what are the basic differences between a democratic country and dictatorial regime.

One more example of using images, creatively, to engage students in discussion about democratic issues, like "Freedom of religion", is an interactive presentation of the famous Russian painting "Boyarynya Morozova" by Surikov (The Spirit of Democracy 2002d). In this painting the artist depicts Feodosiya Morozova, who was an active supporter of the old-believer movement in the Russian church, and a crowd made up of vivid individuals. The image map of the painting is hyperlinked to the close-ups of the individual characters portrayed by the painter. During the class discussion the teacher can, using this interactive image, focus student's attention on different human faces in this complex masterpiece portraying a whole range of attitudes towards religion. This helps to initiate a class discussion about a real historical event and how different people with their own beliefs and values view this event.

The use of multimedia capabilities in this international project is heavily restricted by bandwidth limitations on the Russian partners' side. Russian schools, especially in rural areas, have very slow Internet connections. Due to these bandwidth limitations, in some cases video clips on springboards had to be substituted by a sequence of compressed images and songs were replaced by text. However, the Russian government is currently implementing reforms that encourage the use of modern telecommunications technologies (Filippov, 1999) and the above limitations will soon disappear, allowing a full range of multimedia capabilities.

Interface design and translation tools

It is important to mention a special approach in interface design utilized by The Spirit of Democracy Project. The majority of graphic navigation elements were intentionally designed as hypertext links and not as images. This approach allows the use of automatic translation tools to translate not only the content of individual web pages, but also the navigational elements, thus allowing international users access to the entire content of the Canadian Web site. In the future, with the development of the automatic translation technology, the content of the entire Project site, including Russian web pages, will be available for international users. However, even today, using the Web based automatic translation engine, we provide an option to translate Canadian pages into four languages such as French, Spanish, German and Italian.

The quality of the automatic translation is reasonable, for example the French translation was evaluated and found to be of acceptable quality. However, this is not the case with all languages. For example, when using the service in Spanish, the word "Spirit" in the phrase "Spirit of Democracy" gets translated to the word "alcohol". We believe that, in the future, with the development of better translation tools, these problems will be solved.

It is worthwhile to mention collaborative idea, used in the design a site map, for the Project Web site. In fact, there are two different site maps, for Russian and Canadian sections. Each navigational map provides hyperlinks not only to local pages, but also allows users to navigate the counterpart site, e.g. Canadian site map provides links not only to Canadian pages, but also helps Canadian users navigate the Russian content, and vice versa. This allows users with limited knowledge of a foreign language to explore content on the "foreign" Web site.

Cultural and Copyright issues

This International Web project did not escape certain cultural issues. Most of the issues were related to the Web site design and project logo. At the beginning of the project it was decided that both teams, Russian and Canadian, would develop their own content. In the first three moths of the project a question was raised about designing a logo. The process of logo design is a good illustration of the complex relationship between the two teams. The Project asked a Canadian graphic artist to design a logo for the Spirit of Democracy project. The artist created the first logo based on the existing Russian interpretation of democratic symbols (Figure 3, a). This logo was discussed during the meetings of the Canadian team and was rejected as being not a "true North American democratic symbol" and also having nothing to do with Russia. A second attempt produced a logo that used an image of the Russian "White House" (former parliament building) as a symbol of democracy (Figure 3.b). This logo was accepted by Canadian team, but strongly rejected by Russian team members. Russians argued that government buildings in Russian culture are not associated with symbols of democracy. Finally, the artist created the third version of the Project logo by removing all imagery and blending two national flags in one image with typography as a main graphic element (Figure 3, c). Both teams accepted this logo as a working draft.

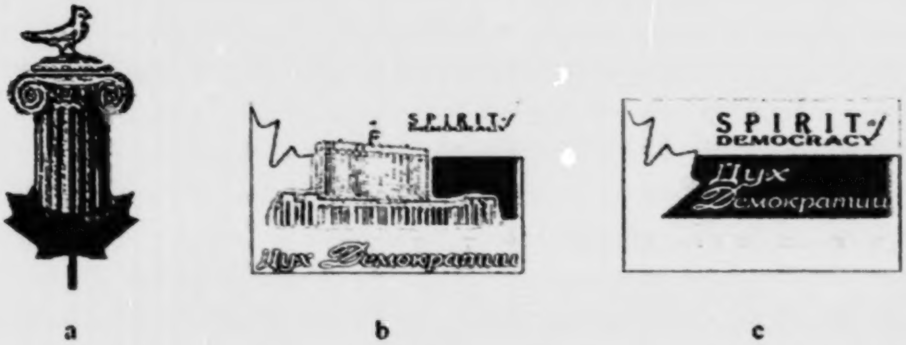

Figure 3: The project logo

Digital Copyright laws in Canada and Russia are different. It is a challenging issue for our Project. So far we are working under the model that all Canadian materials will conform to Canadian digital copyright law, and Russian materials will conform to Russian copyright laws. According to our Russian colleagues, Russian copyright law permits use of any digital materials for educational purposes. What if they decide to use some copyrighted North American materials on the Russian Web site? What copyright law will cover this case?

International collaboration

One of the advantages achieved during the current phase of the project is the creation of working links between Canadian and Russian researchers, teachers, and even students. The links between researchers and teachers, in both countries, began to develop as a result of seminars conducted by Canadian and Russian team members for teachers in Canada and Russia. During the seminars conducted by Canadian researchers in Moscow, Orel and Samara for a total of eighty Russian teachers in the summer of 2001, ten Russian teachers-leaders and their schools were selected for pilot participation in the project. These teachers will receive further training in Canada in the fall of 2002 and will be able to train others in the field of citizenship education. Specialized training, for Russian team members, in web site maintenance and development, will assure that Russian teachers will be able to build upon project outputs and online training materials. Teacher-leaders in the regions of Moscow, Orel and Samara have already conducted their own seminars for other new teachers and for regional school board authorities on the Spirit of Democracy, resulting in materials being incorporated into the curriculum in some areas.

Canadian teachers from all regions of New Brunswick attended a seminar at the University of New Brunswick in November of 2001 on the Spirit of Democracy's educational online materials. After this seminar, teachers of the Superior Middle School in Bathurst, New Brunswick became interested in learning about Russia and currently are working with their administration on development of an integrated curriculum unit that incorporates the study of Russia into all Grade 6 subject areas for one semester. As a result, a strong connection has developed between Bathurst Middle School in Canada and Zelenograd School #1194 in Russia. Canadian students became interested in learning more about Russia, and in exploring issues in the project and communicating with Russian students, and numerous students signed up

BEST COPY AVAILABLE

for the School's Human Right's Club. With the help of their teachers, students of both countries began to communicate with each other and exchanged photograph albums, drawings, and information about themselves and their communities (The Spirit of Democracy, 2002e). The design of the project Web site supports collaboration between students allowing them to participate in online discussions on the Project's discussion board on different topics related to democracy and citizenship. On the discussion board students can write messages in their own language and also follow threads in other languages. However, in order for the discussion board to be an active forum, day-to-day attention and monitoring are required, which was not anticipated in the initial funding proposal.

Conclusions

After two years we can already call this project a success – the Russian team, participating in the project, have developed and posted on the Project Web site more than 50 different topics related to citizenship and democracy, and the Canadian team posted about 30 such topics (The Spirit of Democracy 2002f). Researchers and schoolteachers develop these topics collaboratively. Project materials posted on the Web have already been successfully used by Canadian and Russian teachers in a classroom environment and received positive responses. Several participating Canadian and Russian schools are using project Web-based resources to conduct classes and educate youngsters on democratic values and the spirit of democracy. Currently both, Canadian and Russian teams continue to develop new cases and are planning to meet in the fall of 2002 to discuss their progress and plans for the second phase of the project.

Technology Initiatives in Assessment: National Assessment of Educational Progress (NAEP) Projects in Assessment Design and Delivery of Results

Abstract

The purpose of this panel is to present technology initiatives of the National Assessment of Educational Progress (NAEP) - the only nationally representative and continuing assessment of what America's students know and can do in various subject areas. While NAEP has used technology for a number of different purposes, this panel will focus on two projects: one component of a Technology-Based Assessment project, designed to explore how technology can be used to add efficiency and innovation to the assessment of new and traditional subject matter, and the NAEP website, which uses a number of cutting-edge web-based tools to report assessment results to the public.

Background Context

As the only nationally-administered assessment program, NAEP plays a critical role in President Bush's No Child Left Behind national and state educational reform initiatives. Given NAEP's role in these initiatives, the assessment development, administration, scoring, and results dissemination processes are of increasing interest to state testing programs and educators.

Under current law, the Commissioner of Education Statistics, who heads the National Center for Education Statistics in the U.S. Department of Education, is responsible for carrying out the NAEP project. The National Assessment Governing Board, appointed by the Secretary of Education but independent of the Department of Education, governs the program.

NAEP does not provide scores for individual students or schools; instead, it offers results regarding subject-matter achievement, instructional experiences, and school environment for populations of students (e.g., fourth-graders) and subgroups of those populations (e.g., female students, Hispanic students). NAEP results are based on random national and state school and student samples.

The NAEP Website

The NAEP has taken a number of innovative steps to leverage the technology afforded by the WWW to make NAEP data on student achievement and background variables related to that achievement readily available to the public. In addition to extensive web pages that detail information about the program and specific assessment results, the site features complex web-based tools that allow users to access a complex "results" database, perform statistical significance tests on specific results, produce both tabular and Scaleable Vector Graphics (SVG) of assessment data, and view/print assessment questions, scoring guides and sample student responses.

The panel will discuss and demonstrate the following technology initiatives on the NAEP website

(1) Overall Architecture of Site - Program information, results pages, applications

(2) Applications

   a. The NAEP Data Tool: Comprehensive 50GB database of assessment results of 7 subjects and over 10 years of assessment data. (Civics, Geography, U.S. History, Reading, Mathematics, Science, Writing). We will demonstrate the following:
      - the process/challenge of making results web-deliverable
      - the role of the database as an underlying foundation of the NAEP website
      - how the database feeds? other applications on the site (State Profiles)
      - the introduction of SVG into the tool
      - Report -generator as the next step (natural language x)

   b. The NAEP Questions Tool

      - Demonstration of the web-based tool that allowers users to access and print released assessment exercises, scoring guides, student responses and questions-level data.

(3) Future Projects
   - State Reporter Generator
   - Data Mining

The Technology-Based Assessment Project: the Technology-Rich Environment Study

The Technology-Based Assessment (TBA) project is designed to explore the use of technology, especially the use of the computer, as a tool to enhance the quality and efficiency of the NAEP. To help understand how the ever-increasing use of computer technology in schools and the work place will impact NAEP assessments, the project is exploring the following key questions about TBA:

- What are the measurement implications for NAEP?
- What are the equity implications?
- What are the efficiency and cost implications?
- What are the operational implications?

- How can we best incorporate new technology into NAEP in both the short and long term?

The panel will begin with a general description of the TBA project and its goals, including a discussion of the Math Online and Writing Online projects, designed, respectively, to measure current NAEP math and writing content using a web-based delivery system. The panel will then focus on the Technology-Rich Environment Study, one component of TBA. The TRE project is designed to model possible ways NAEP can assess student abilities to solve complex problems using technology-based tools. To date, two model tasks have been created, one requiring students to solve a physics-based problem using a web-based simulation, and the other requiring students to search a quasi World Wide Web universe to find and synthesize relevant information about a physical science topic.

Pilots in New Jersey schools and pretesting of a national convenience sample have demonstrated that both tasks are viable and meaningful ways of assessing student's problem-solving skills using web-delivered technology.

The panel will discuss what each task intends to measure, describe the process of task development, demonstrate some part of each task, and conclude with a discussion of how student responses will be scored.

Presenters:

First, some background clarification about the organizational structure of the NAEP project. NAEP is funded by the Department of Education, under the auspices of the National Center for Education Statistics (NCES). Development, analysis and reporting of NAEP assessments are performed under contract with Educational Testing Service (ETS). ETS develops applications and content for the NAEP website and manages the day-to-day operations of the NAEP public website (http://nces.ed.gov/nationsreportcard)

Madeline Goodman is the Project Manager for the NAEP website. She has worked at NAEP for 5 years, as History and Social Science Coordinator before moving on to produce and manage the production of NAEP content on the web. Ms. Goodman has a doctorate in U.S. History. She has worked with programmers, research scientists, graphics artists and interface designers to coordinate numerous large-scale projects for the NAEP website. She has a working knowledge of all areas of the website and its role within the education and government communities. Madeline has worked at Educational Testing Service for 7 years.

Jeffrey Jenkins is the NAEP Webmaster, responsible for managing the technical side of the NAEP website. He has an extensive background in all areas of website management, including user-interface design, programming, content management/systems design and database management. He has worked on the NAEP project for three years and at Educational Testing Service for 10 years.

Hilary Persky is a senior Program Administrator at NAEP. She has worked at NAEP for 8 years on numerous projects, including History/Social Science assessments and the NAEP Arts and Writing assessments. Her current major responsibilities include overseeing and managing the NAEP Writing assessment and the Technology Rich Environment (TRE) portion of the Technology Based Assessment project. She had major responsibility for developing the content of the current TRE project. Ms. Persky has worked at Educational Testing Service for nearly 10 years.

Modules and Information Retrieval Facilities of the Human Use Regulatory Affairs Advisor (HURAA)

Abstract: The Human Use Regulatory Affairs Advisor (HURAA) is a web-based facility that provides help and training on the ethical use of human subjects in research, based on documents and regulations in United States Federal agencies. HURAA has a number of standard features of conventional web facilities and computer-based training, such as hypertext, multimedia, help modules, glossaries, archives, links to other sites, and page-turning didactic instruction. HURAA also has more intelligent features: (1) an animated conversational agent that serves as a navigational guide for the web facility, (2) lessons with case-based and explanation-based reasoning, (3) document retrieval though natural language queries, and (4) a context-sensitive Frequently Asked Questions, called *Point & Query*. This paper describes the major modules and features of HURAA and evaluates the performance of document retrieval through natural language questions.

Introduction

The Human Use Regulatory Affairs Advisor (HURAA) is a web-based facility that provides help, training, and information retrieval on the ethical use of human subjects in research. The content of HURAA is derived from

Federal agency documents and regulations, particularly the National Institutes of Health (NIH, 45 CFR 46), the Department of Defense (32 CFR 219, DoD Directive 3216.2), and particular branches of the US military. The users of the HURA Advisor are high-ranking military officials who must approve research protocols involving human subjects in studies sponsored by the Department of Defense (DoD). These users focus on fundamental ethical issues, but not the detailed procedures and paper work associated with gaining approval from Institutional Review Boards.

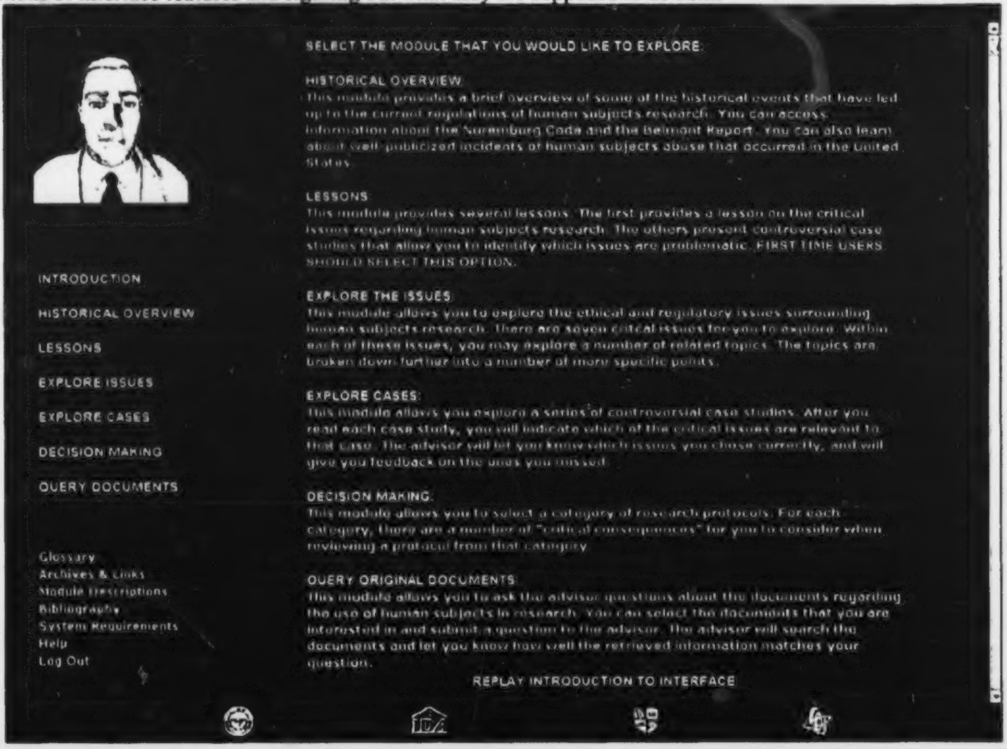
The design of HURAA was guided by a number of broader objectives. First, the layout and design of the web facility incorporate available guidelines in human factors, human-computer interaction, and cognitive science. Such guidelines are advocated by the Advanced Distributed Learning (ADL) Initiative of the DoD. Second, the architecture of the HURAA components needed to be conformant with the ADL standards for reusable instructional objects, as specified in the Sharable Content Objects Reference Model (SCORM 2001). The primary objective of having these standards is to allow course content to be shared among different lesson planners, computer platforms, and institutions. Third, HURAA was designed to optimize both learning and information transmission. High ranking military personnel have very little time, so it is imperative to promote the speed and quality of learning in web-based distance learning environments (Tobias & Fletcher 2000, SCORM 2001). This requires careful consideration of the pacing of the information delivery, the selection of content, and design of the tasks to be performed. Fourth, HURAA incorporated some of the sophisticated pedagogical techniques that have been implemented in intelligent tutoring systems (ITS) during the last two decades (Anderson, Corbett, Koedinger, & Pelletier 1995, Graesser, VanLehn, Rose, Jordan, & Harter 2001, VanLehn, Jones, & Chi 1992). Some of the lessons and modules had case-based, explanation-based, and question-based learning mechanisms in an effort to promote deeper mastery of the material. Fifth, the web site was supposed to be engaging to the user. HURAA incl,uded some persuasive multimedia that was intended to hook the user to continue on the website (Mayer 1997).

A sixth general objective was to optimize information retrieval when users actively attempted to search for information. Some users prefer to learn by actively exploring information, asking questions, and accessing answers to questions (Graesser & Person 1994, Graesser & Wisher 2001, Otero & Graesser, 2001), whereas many learners are more passive and rarely pose questions. A good web facility provides information quickly on demand for those occasions when users are curious, active, self-regulated learners. HURAA implements multiple methods of accessing information in a large space of documents. HURAA has hypertext and glossaries, which are conventional methods of information retrieval. But HURAA does not stop there. HURAA has a *Point & Query* facility (Graesser, Langston, & Baggett 1993), which provides answers to context-sensitive Frequently Asked Questions (FAQs). HURAA also accesses documents that provide answers to questions that the user formulates in English, using techniques in computational linguistics (Jurafsky & Martin 2000, Landauer, Foltz, & Laham 1998). It is the latter facility (i.e., document access via queries in natural language) that will receive primary attention in the present article. We will assess the performance of our natural language document retrieval facility in supplying informative and relevant information.

In summary, there are two goals of the present article. First, we present a snapshot of the modules of HURAA, with particular attention to those that provide information retrieval. Second, we report performance on our natural language document retrieval facility.

Modules and Features of the HURA Advisor

The home page of HURAA is presented below (Fig. 1). There are seven primary modules and seven secondary modules. Labels for these modules are presented in the left banner of the HURAA web page. The main display area in the middle of Figure 1 describes primary modules of HURAA. The interchange between the user and the HURAA is managed by an animated conversational agent (see upper left corner) and by discourse mechanisms that are designed to facilitate the dialogue (Graesser, Person, Harter, & TRG 2001, Graesser et al. 2001, Person, Graesser, Kreuz, Pomeroy, & TRG 2001). Many users will be high-level decision-makers with very little time to visit the site (i.e., 30 minutes or less) so HURAA needs to be engineered to maximize its coverage of critical information in the minimum amount of time. This requires some efficient dialog management techniques that are available in the fields of human-computer interaction and discourse processes. For example, the conversational agent briefly identifies the functions of major interface components the user clicks on, and offers recommendations on next steps when each web page is first accessed. This prevents the first-time user from spending undue time analyzing the functions of interface features and figuring out what they are supposed to do next.



SELECT THE MODULE THAT YOU WOULD LIKE TO EXPLORE:

HISTORICAL OVERVIEW:
This module provides a brief overview of some of the historical events that have led up to the current regulations of human subjects research. You can access information about the Nuremburg Code and the Belmont Report. You can also learn about well-publicized incidents of human subjects abuse that occurred in the United States.

LESSONS:
This module provides several lessons. The first provides a lesson on the critical issues regarding human subjects research. The others present controversial case studies that allow you to identify which issues are problematic. FIRST TIME USERS SHOULD SELECT THIS OPTION.

EXPLORE THE ISSUES:
This module allows you to explore the ethical and regulatory issues surrounding human subjects research. There are seven critical issues for you to explore. Within each of these issues, you may explore a number of related topics. The topics are broken down further into a number of more specific points.

EXPLORE CASES:
This module allows you explore a series of controversial case studies. After you read each case study, you will indicate which of the critical issues are relevant to that case. The advisor will let you know which issues you chose correctly, and will give you feedback on the ones you missed.

DECISION MAKING:
This module allows you to select a category of research protocols. For each category, there are a number of "critical consequences" for you to consider when reviewing a protocol from that category.

QUERY ORIGINAL DOCUMENTS:
This module allows you to ask the advisor questions about the documents regarding the use of human subjects in research. You can select the documents that you are interested in and submit a question to the advisor. The advisor will search the documents and let you know how well the retrieved information matches your question.

Figure 1: Home Page of HURA Advisor

Major Modules

The seven modules of HURAA are enumerated below. Links for these seven modules are always present on the web page, in the banner on the left (Fig. 1).

(1) *Introduction*. The Introduction Module is a multimedia movie that plays immediately after a new user has logged in. It is designed to impress the user with the importance of protecting human subjects in research. It describes for the user "what" the site is, "who" should use the site, "why" the site is important, "how" the site works, and "when" the site should be used. It consists of a "voice-over" accompanied by images.

(2) *Historical Overview*. This module contains an additional multimedia movie highlighting some of the most famous abuses of human subjects in history. There are different options for the user to select, in a standard hypertext/hypermedia organization that allows the user to "drill down" to learn more about those topics. Users can also access information through Point & Query (Graesser et al. 1993) or a natural language query facility, as described later.

(3) *Lessons*. This module comprises four lessons that teach the user about the Seven Critical Issues relevant to ethical violations that were identified by Emmanuel et al. (2000). User learns how to apply them to particular cases that involve ethical abuses. After a case is presented, the user is then presented with the Seven Critical Issues and must decide, on a six-point scale, the extent to which there is a problem with each issue in that case. The user then receives feedback comparing his/her responses with those of a group of experts from the DoD, along with a brief explanation. Discrepancies are highlighted in red. This is a form of case-based reasoning, which is recognized to be

BEST COPY AVAILABLE

appropriate for legal and ethical reasoning (Ashley 1990). Cases are dynamically selected on the basis of the user's previous responses, to ensure full coverage of the Seven Critical Issues.

(4) *Explore Issues*. This module expands the Seven Critical Issues into a number of topics and points, hierarchically organized in a hypertext system. The user drills down to learn more specific information about particular issues. Point & Query and natural language queries are also available.

(5) *Explore Cases*. This module has approximately 40 cases used in both the Lessons and Explore Issues modules. The user can drill down to see cases associated with a three-level hierarchy of issues, sub-issues, and sub-sub-issues.

(6) *Decision Making*. The Decision Making module is designed for those who need information about a specific category of protocol (e.g., drug studies, surveys). The user is presented with a list of protocol categories. Selecting one of the categories presents the user with a list of several "critical consequences," i.e., negative results that may occur from an incorrect decision. Selecting one of the critical consequences presents the user with a more complete description of a consequence associated with an incorrect decision.

(7) *Query Documents*. This module allows the user to ask a natural language question (or description) and then retrieves excerpts from various documents and HURAA content. The user can select any or all off several documents to search. For each document that the user selects, the top result selected by the computational linguistics software is displayed in a window. Beneath this window, the headings for the next four results appear. If the top choice is not the one that the user needs, s/he can click on the headings to read those excerpts. The search is driven by mechanisms described later in this article.

Secondary Modules

In addition to the seven major modules in HURAA, there are seven secondary modules that supplement the primary content and help the individual use the site.

(8) *Glossary*. The Glossary contains over 200 terms relevant to human subjects research. The user may either browse the alphabetized listing or search by entering a term. Additionally, throughout HURAA, glossary terms are highlighted and the user may click on the term to see the definition or a list of related terms.

(9) *Archives & Links*. This module contains links to military regulations and relevant civilian documents. There are links to external web sites of military and nonmilitary organizations, and of online tutorials. Original documents are needed when the user has to access the exact text that stipulates policies and procedures.

(10) *Module Descriptions*. This module contains text descriptions for each of the primary modules. It is a good single-page overview of what HURAA has to offer in training.

(11) *Bibliography*. This lists relevant resources, including references for the content of HURAA and other publications that are relevant to the protection of human subjects in research.

(12) *System Requirements*. This module contains links to download necessary software components for running HURAA. This page appears automatically at the beginning of a new user's session. It remains available in case a user is having problems with particular HURAA components.

(13) *Help*. This has helpful hints for users who are having problems navigating HURAA.

(14) *Log Out*. The user logs off the web site when the user clicks on this.

Navigation and Information Retrieval Features

HURAA has a number of features that support diverse methods of navigation and information retrieval. In addition to the traditional features of web sites (such as Graphical User Interfaces and Hypertext drill down), there are a number of unique intelligent features that are now just starting to be used on web sites: an Animated Conversational Agent, Point & Query, and Natural Language Query.

It is convenient to view the various forms of navigation and information retrieval from the perspective of the five approaches to navigation discussed by Quesenbery (2001). The different forms of navigation and retrieval that exist in each of the modules and features of HURAA are identified below (Tab. 1).

1. *Browsing – "I want to see what's available."*
2. *Finding – "I want to locate something specific."*

3. *Query – "I want to see items that meet my criteria."* Query navigation is supported in the Query Documents module and other modules by allowing the user to ask a natural language question. Query navigation is also supported by the P&Q option, although the queries are limited to those provided by HURAA. The advantage of P&Q is that the user can ask sophisticated questions and receive answers specifically tailored to those sophisticated questions, rather than risking a bad search result.
4. *Structured - "I want to be led through a series of choices to help me narrow my focus."* .
5. *Guided – "I want to be led through the information."*

Table 1: Forms of Navigation and Retrieval for Different HURAA Modules & Features

Animated Conversational Agent

This is a talking head with synthesized speech, facial expressions, and pointing gestures. The Agent tells the user what to do next when the user first encounters a web page. For example, when the user enters the Explore Issues Module, the Agent says, "Select the issue that you would like to explore." The talking head moves to direct the user's attention to some point on the display. For example, the talking head looks down when he says, "You may select one of the options below me." The talking head also tells the user what each primary and secondary module is supposed to do, after the user rests the mouse pointer over the module link for more than 2 seconds. The Agent is designed to project an authoritative persona and to help the user navigate through the interface more quickly. Many novice users are lost and don't know what to do next when they encounter a page. The Agent is designed to reduce this wasted time.

Point & Query

The interface displays a question mark (?) for some hot spots. When the user clicks on the question mark, a menu of questions appears. The user selects a question by clicking on it, and then the answer appears. Thus, the user can quickly ask a question with two clicks of a mouse. Users are also exposed to good, relevant questions because the designer of the P&Q handcrafts these Question-Answer items. P&Q can be viewed as a context-sensitive Frequently Asked Question (FAQ) facility.

Natural Language Query

The user can ask a question by typing it in English. The English description can be an interrogative or declarative expression of any arbitrary length. The user can declare what document or set of documents to search for an answer. HURAA accesses 5 paragraphs from the source documents that should contain relevant information to the query. The highest matching document identified by the computational linguistics software is automatically presented; selections 2-5 have a brief description presented, with an option for the user to view any of these paragraphs in their entirety.

Evaluation of Performance of Natural Language Queries

The natural language query feature is the most direct form of information retrieval because the user does not need to depend on or wait for the web content and interface to set the stage for posing a particular question. The user simply asks the question in English, at any point in the session with HURAA. In contrast, all of the other information retrieval facilities require the user to sift through the web pages, menu options, or hypertext hot spots until the right point when a particular question can be posed, if indeed it can be posed at all. Because of this special status of the natural language query feature, we conducted a performance analysis on how well different search engines fetched relevant and informative information. A natural language query facility is useful to active learners only to the extent that it provides relevant, informative information.

We tested 8 search engines, consisting of all combinations of the presence or absence of the following three match functions: (1) Latent Semantic Analysis (called *LSA*), (2) frequency-weighted keyword matching (called *Keyword*), and (3) glossary word matches (called *Glossary*). Each match function produces a value of 0 to 1 when considering the overlap between the words in query Q and the words in paragraph P. The paragraph that has the highest overlap, i.e., max {overlap(P,Q)}, is returned when one of the three functions is considered. When multiple match functions are considered (such as LSA+Glossary), then the paragraph is selected that has the highest average match values from the multiple functions.

Latent Semantic Analysis (LSA)

Latent Semantic Analysis (LSA) has recently been proposed as a statistical representation of a large body of world knowledge (Landauer, Foltz, & Latham 1998). The LSA uses a statistical method called "singular value decomposition" (SVD) to reduce a large Word by Document co-occurrence matrix to approximately 100-500 functional dimensions. The Word-by-Document co-occurrence matrix is simply a record of the number of times word W_i occurs in document D_j. A document may be defined as a sentence, paragraph, or section of an article. Each word, sentence, or text ends up being a weighted vector on the K dimensions. The "match" (i.e., similarity in meaning, conceptual relatedness) between two unordered bags of words (single words, sentences, or texts) is computed as a geometric cosine (or dot product) between the two vectors, with values ranging from 0 to 1. From the present standpoint, LSA is used to compute the highest matching paragraph from the document space that is relevant to the question Q.

Word frequency weighted keyword matching (Keyword)

HURAA has a lexicon with word frequency norms that are available electronically (Francis & Kucera 1982). The frequency of usage is the number of times the word occurs in a representative sample of printed text in the English language. Rare words should have higher weight than frequent words because they are more distinctive. Therefore, each word W_i is weighted according the reciprocal of is word frequency value $fr(W_i)$: $[1/fr(W_i)]$. An overlap score is computed that reflects the proportion of words that overlap between question Q and paragraph P (weighted by the reciprocal of the word frequency).

Glossary word matches (Glossary)

Glossary words are defined as all words in the HURAA glossary. These are technical words and terms relevant to the ethical use of human subjects. An overlap score is computed that reflects the proportion of glossary words that overlap between question Q and paragraph P.

Three experts on research ethics were instructed to generate 20 questions about four sections of the subject matter of HURAA (80 questions total). For each question, there were 8 paragraphs as answers, corresponding to the 8 search engines. The experts judged whether or not each paragraph was relevant to the question (Relevance Judgment) and an informative answer to the question (Informativity Judgment). The performance of the search engine was scored as the proportion of paragraph answers that were judged as relevant or informative. The mean proportion scores are presented below (Tab. 2).

The different search engines clearly yielded different affects on relevance and informativity proportion scores. A one-way ANOVA was found to show statistically significant differences in relevance proportion scores as a function of search engines, $F(7, 88) = 21.03$, $p < .01$, $MSe = .02$, as well as differences in informativity proportion scores, $F(7, 88) = 17.29$, $p < .01$, $MSe = .02$. The keyword match function was the clear winner, and significantly higher than each of the other seven search engines. Interestingly, about 2/3 of the fetched paragraphs were perceived as relevant and informative when the keyword search engine was used. This performance is quite impressive. It supports the claim that the performance of the natural language query module is sufficiently impressive that it should be a worthwhile information retrieval facility for active learners who like to ask questions.

SEARCH ENGINE	Relevance	Informativity
LSA	.40	.48
Keyword	.64	.66
Glossary	.19	.22
LSA+Keyword	.55	.56
LSA+Glossary	.26	.30
Keyword+Glossary	.36	.38
LSA+Keyword+Glossary	.37	.39
Random	.06	.08

Table 2: Relevance and Informativity Proportions for Eight Search Engines for Natural Language Queries

Learning from Hypertext and the Analyst-Intuition Dimension of Cognitive Style

Martin Graff
School of Humanities and Social Sciences,
University of Glamorgan,
UK
Mgraff@Glam.ac.uk

Abstract: **From an instructional perspective, it is conceivable that employing an appropriate hypertext architecture should have the advantage of facilitating learning by representing logically the interrelationships between different units of information contained within the hypertext. Furthermore, there would however appear to be a sound theoretical rationale for suggesting that the degree to which hypertext based instructional systems facilitate learning will be contingent on an individual's cognitive style. This study aimed to investigate the effects of hypertext architecture and cognitive style on learning. Fifty three participants were assigned to one of three hypertext architectures corresponding to linear, hierarchical and relational structures. Cognitive style was assessed using the Cognitive Styles Index (Allinson and Hayes, 1991). The findings revealed an interaction between cognitive style and hypertext architecture on the recall performance of participants. However, when learning was assessed at a deeper level, no significant effects were observed. Further analysis revealed that concept maps of the hypertext architecture differed between participants in each hypertext condition. The results are discussed in terms of a consideration of individual differences in cognitive style in the design of hypertext instructional systems.**

Introduction

System structure has been found to affect navigational performance within a hypertext environment (McDonald and Stevenson, 1996, 1998), and this in turn has been found to influence learning (Shapiro, 1998; Tripp and Roby, 1990).

The potential benefits of hypertext to learning may also be influenced by employing different hypertext architectures for instruction. There is evidence to suggest that learning performance is enhanced when mixed hypertext architectures are employed (Mohageg, 1992; McDonald and Stevenson, 1998, Shapiro, 1998). In these studies mixed hypertext architectures were hierarchical with lateral links. However, a further question may be posed here, which is whether individual differences between learners can influence performance within particular hypertext architectures.

One individual difference characteristic which would appear to be relevant to learner performance in hypertext, is cognitive style. Field dependence-independence is one of the most extensively researched formulations of cognitive and evolved from Herman Witkin's pioneering work on perception of the upright. With regard to the relationship between cognitive style, hypertext and learning it is likely that the complex hypertext structures, predisposes that individuals possessing a style which facilitates their ability to apprehend such structures when browsing may derive greater benefit in terms of learning from hypertext. Results generally reveal that field independent individuals outperform field-dependents in the recall of verbal information from a hypertext delivery (Lin and Davidson-Shivers, 1996), and also that performance of field independents is superior when using explicitly structured hypertext (Korthauer and Koubek, 1994). However, one alternative explanation for these results is that the Group Embedded Figures Test (GEFT) used to measure field dependence-independence has also been found to be correlated with standard ability tests (Verbon, 1972; McKenna, 1984).

Other studies to date have used different psychometric tests of style in order to test the relationship between style and the effectiveness of instruction delivered via hypertext. For example, Melara (1996) used Kolb's Learning Style Inventory and Beishuizen, Stoutjesdijk and van Putten (1994) and Verhejj, Stoutjesdijk and

BEST COPY AVAILABLE

Beishuizen (1996) using a formulation of the deep and surface processors construct. Many of these studies used recall performance as a measure of learning, yet most academic concepts are more complex requiring a level of learning deeper than is demonstrated by mere recall.

This study aims to assess whether different hypertext architectures are more facilitative to individuals with different cognitive styles and employs a psychometrically sound instrument for the assessment of cognitive style. Furthermore, learning in this study is assessed at a deeper level than mere recall of information from the hypertext.

Method

Participants

55 participants took part in this study, 46 male and 9 female undergraduate students, with a mean age of 22.93, an SD of 6.21, minimum age of 19 and maximum age of 47.

Hypertext

The subject matter of the hypertext document was taken from various pieces of historical information and edited so that the names dates and events were altered in order to maintain consistency. Each page of hypertext, typically contained between one and four sentences of information. The document consisted of 64 nodes or pages containing 3388 words.

Three hypertext document was presented as one of three architectures corresponding to linear, hierarchical and relational. A description of each architecture is outlined below. Diagrams of the hypertext architectures employed are shown below in Figs 1 to 3.

In the linear architecture, the hypertext pages were linked such that the user could move only to the next or the previous page. Each page however had a link to the first page, and the first page had a link to the top page of each of the four general sections within the structure. In this way the structure resembled a book structure, in that the user could start at a contents page, and move to the beginning of any chapter, and similarly from the middle of any chapter could jump back to the contents page again (see Figure 1). The linear architecture comprised 66 links between pages.

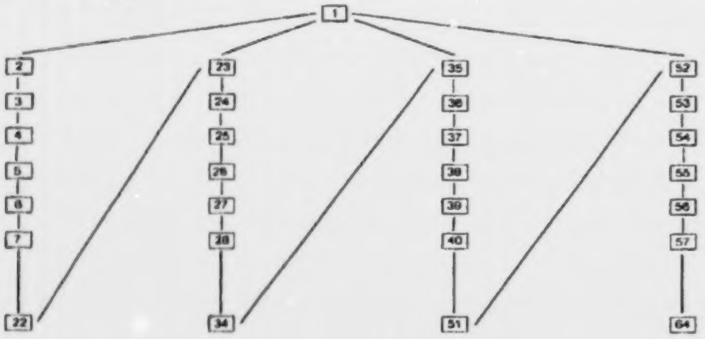

Figure 1: Linear Architecture

The hierarchical architecture was designed so that a user could move from reading a page at one level, down to a page below it in the hierarchy, or back to a page above it in the hierarchy. In this hierarchical architecture, general concepts subsumed more detailed ones. Users could move up and down the hierarchy, exploring subordinate and superordinate relationships. However, no facility was provided for lateral moves (See figure 2). The hierarchical architecture was comprised of 62 links.

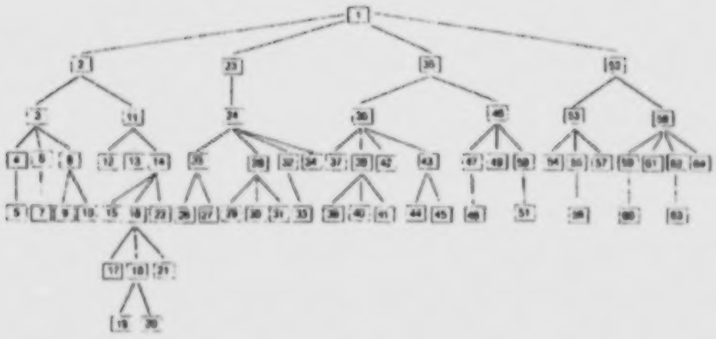

Figure 2: Hierarchical Architecture

The relational architecture was identical to the hierarchical architecture, in that users could move up or down the hierarchy. However, this structure also contained additional links, which meant that the user could move laterally to other locations within the architecture, related by subject matter (see Figure 3). The relational architecture was comprised of 62 links plus a further 32 lateral links.

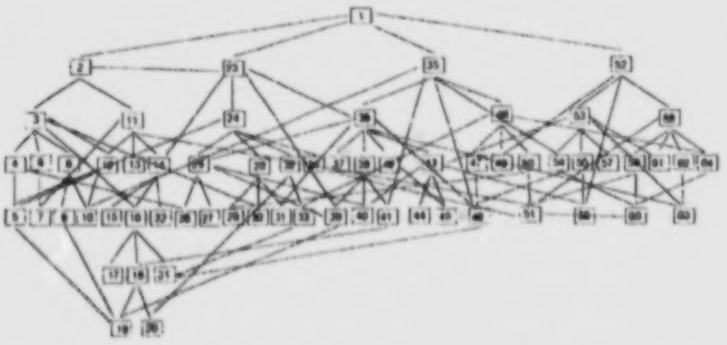

Figure 3: Relational Architecture

Assessment of Cognitive Style (Cognitive Styles Index) (Allinson and Hayes, 1991)

The Cognitive Styles Index is a test of cognitive style developed for large scale use. It determines an individual's position on the analyst-intuitive dimension of cognitive style. Typically analysts are able to apprehend ideas or concepts in parts, but have difficulty integrating such ideas into complete wholes. However, intuitives are able to view ideas as complete wholes, but are unable to separate these ideas into discrete parts. Scores on the CSI can range from 0 up to 76. Analysts can be identified by a low score on this test, while intuitives may be identified by a high score.

Procedure

Participants were assigned to one of the three hypertext architecture conditions, and were asked to read through the hypertext pages in any order they chose, provided that this reading order could be accommodated

BEST COPY AVAILABLE

by the hypertext architecture to which they were assigned. They were then tested in three ways. Firstly with ten recall questions, secondly by writing an essay which could be answered from the information in the hypertext and finally by drawing a map of the hypertext architecture they had used.

The recall test was scored by simply adding up the number of correct answers to questions on information within the hypertext. Each essay was assessed in terms of the amount of detail it contained and also how well each participant had integrated the information content in the essay. Maps produced by participants were scored in terms of complexity and density measures. The formula for the calculation of complexity as given by Johnson, Gregory and Smith (1986) is links drawn / nodes drawn. The formula for calculation of density as given by Klein and Cooper (1982) is links / nodes (nodes – 1).

Results

Table 1 displays the results of an analysis of variance for recall questions for architecture and cognitive style, with the means and standard deviations displayed in Table 2. No significant main effects can be observed for architecture and cognitive style, although a significant interaction effect is evident between architecture and cognitive style. Inspection of the table of means reveals variation between cognitive styles within each architecture condition.

Table 4: Means and standard deviations for detail and integration scores

Table 5 displays the results of an analysis of variance for essay detail and integration scores for architecture and cognitive style, with the means and standard deviations displayed in Table 6. A significant main effect can be observed for architecture on the density, F (2,35) =4.43, p = 0.01. Inspection of the means scores in Table 6 reveals that participants performing in the relational architecture condition score highest on density scores. Tukey's test of post-hoc comparisons, reveals significant differences in complexity scores between participants in the relational and hierarchical architecture conditions ($p<.01$), however, no differences were observed between relational and linear conditions or between hierarchical and linear conditions for complexity. For density scores, the main effect for architecture is approaching significance, F (2,35) = 2.80, p = 0.07. Finally, an interaction effect approaching significance between architecture and cognitive style can be observed F (4,35) = 2.24, p = 0.08.

Discussion

This study examined several issues regarding cognitive style and learning from hypertext. Firstly, a significant interaction was observed between cognitive style and hypertext architecture for recall questions. While it is conceded that recall does not represent an effective measure of learning, the results go some way to suggesting that individuals possessing different cognitive styles learn more efficiently from certain hypertext architectures. This finding is in accord with the cognitive styles matching hypothesis.

The cognitive style matching hypothesis essentially suggests that when the cognitive styles of the system and the user are matched, then the amount of learning will be improved. An illustration of the interaction between a teacher's and learner's cognitive styles is given in the diagram below. (see figure 4).

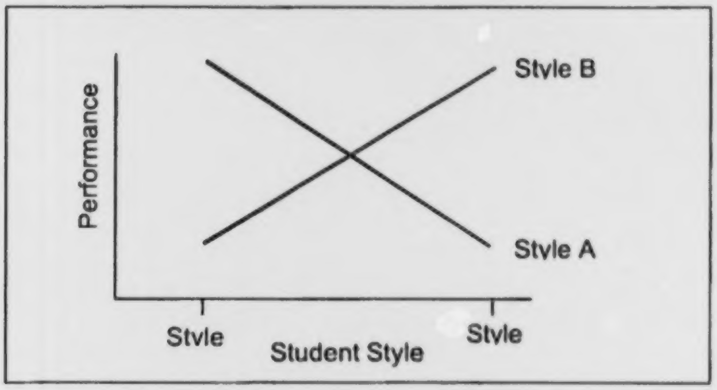

Figure 4: Theoretical interaction between learner's and teacher's cognitive styles

In this respect, hypertext appears to offer promise to such a matching hypothesis, as the architecture may be designed with consideration to the cognitive style of the user.

No differences were found on assessment of detail and integration in the essay question for hypertext architecture or cognitive style. This somewhat calls into question the previous results, although it is equally possible that the scoring system employed for the essay question needs further refinement.

A significant effect was observed for complexity scores for architecture, with participants in the relational architecture producing significantly more complex maps than those performing in the other two conditions. This may be accounted for by the fact that the relational condition had more hypertext links than each of the other two conditions. Finally differences were observed for density scores between architectures and furthermore an interaction effect was also observed here. As density scores approach 1 the map's density increases as it approaches optimal connectivity. In this study map density was used as an indication of the degree to which participants had integrated the individual concepts within the subject domain. However, the effects here are only approaching significance.

At least two important methodological points need to be considered in future studies. Firstly, it is possible that individuals may engage differently with certain types of information depending on their cognitive styles. Therefore a different type of information content may possibly give different results. Therefore the type of information featured in the hypertext also needs to be considered. Secondly, in this investigation, learning was measured by scoring essays for level of detail. It is relevant also to consider other methods of learning in future studies.

Conclusion

It is tentatively suggested that the results revealed in this study may be applied in the context of matching hypertext architecture to the cognitive style of the user in order to facilitate more effective learning. This therefore has important implications for e-learning as it is possible that individuals may benefit by using hypertext architectures designed to take account of their particular cognitive styles. Hypertext would appear to offer great promise to such a matching, as these systems may be designed with consideration to the cognitive style of the user, and their ability to effectively apprehend the structure of the system and also to perceive their correct orientation.

Department of Education
St. John's University
United States
danielst@stjohns.edu

Abstract: A problem facing many supervisors and administrators in K-12 and higher education is how to effectively integrate technology into the instructional program. Professional development plays a key role in providing training and support required to develop the instructional technology (IT) skills necessary to have a positive effect on instruction. This paper will explore the role of supervisors and administrators as instructional leaders in their schools in the formation and support of programs aimed at the integration of instructional technology. An online professional development course for supervisors was developed by the principal of a large urban high school in the northeast, using Blackboard as the vehicle for the course's implementation. The goal of the course was to provide turnkey training for the ten assistant principals at the school. In addition to providing some essential IT skills for the supervisors and administrators, the online course aimed to begin to cultivate a community of learners within the school.

Teaching and Learning in the 21st Century

There have been many notable changes in our society as we move forward into the 21st century. Basic philosophical changes in teaching and learning have dominated the educational landscape. According to Schlechty (1997) the way people access, work with and communicate information is fundamentally different than it was a decade ago. Education and teaching are no longer seen as a method of delivery of information. Kavanagh (2001) believes that educators have had to make a radical shift in their approach to teaching and learning, and must focus more on the process by which students learn. A true educator is no longer viewed as the center of attention and does not merely impart knowledge to the eager-to-learn student. Barth (2001) contends that the "Transmission of Knowledge" model fails to meet the needs of students to be involved and engaged learners. In the effective classroom, the true educator serves more as a coach and facilitator who draws forth learning from within the student.

Schlechty (1997) stresses that in order to shift attention from teacher to learner, teachers must plan lessons that are more interactive and more student-centered. This shift in attention toward the student also requires a more learner-centered approach to curriculum writing and revision.

The Role of Technology in Teaching and Learning

In the past two and a half decades, technology has become an integral part of classroom instruction. This technology has been computer based. Only ten years ago, there was approximately 1 computer for every 30 students in the United States. In 2000, that figure dropped to 1 computer for every 4.9 students (Education Week, 2001). Educators across this country and around the world have recognized that computers have a genuine place in the education of our children. As Lemke and Coughlin (1998) point out, technology accelerates, enriches and deepens basic skills; it motivates and engages students in learning.

In recent years, as the computer has found its way into more classrooms, a myriad of uses has developed. While early classroom use was relegated to BASIC programming, today's uses include traditional computer applications such as word processing, database management, use of spreadsheets, presentation software, and computer graphics, as well as more advanced programming, web design, and other web-based applications such as online research and e-mail.

As computers and access to the Internet become more widespread in schools and homes of students and teachers, technology has become a tool that is quickly changing the way teachers teach and the way in which students learn. According to Fisher and Dove (1998) we are clearly in a period of transformation. To move forward will require leadership, vision and a willingness to take risks and to make mistakes for the opportunity of improving instruction and increasing learning in our students. As Schmeltzer (2001) notes, administrators can no longer avoid providing the same leadership in technology as they have in the more traditional areas.

Access Issues for Staff and Students

While embarking upon professional development programs to train teachers and administrators in the use of the computer as a technology tool for teaching and learning, we need to understand that there may be access issues for teachers as well as for our students. Do our administrators, teachers and students have computers readily available to them in the schools? What about at home? In addition, how many of these computers have Internet access?

The answer to the access question is that, in general, most teachers have access to a computer. In a recent study by the National Center for Educational Statistics (2000) virtually all (99 percent) public school teachers reported having access to a computer somewhere in their school. In addition, the NCES cited that 82 percent of public school teachers reported that there was a computer available to them at home. However, access to the Internet is much less widespread - only 63 percent of those responding to the NCES study had Internet access.

Having access to a computer, though, does not guarantee its usage in the classroom. According to the NCES study (2000), only half of the teachers who had computers or the Internet available in their schools used them for instructional purposes.

The Role of the Supervisor

To effectively integrate educational technology into the learning environment, Gibson (2000) points out that it is essential for informed and effective leadership to have a visible presence. Serving as the instructional leaders in their buildings, administrators and supervisors must provide the means and professional development necessary to achieve technology infusion and to ensure that computers and the Internet are optimally utilized. In order to do so, it is essential that all administrators and supervisors become technologically competent. As Gillingham and Topper (1999) assert, administrators of teacher prep programs need to learn more about modern forms of communication and IT, and to make them an integral part of their programs.

One of the main frustrations of teachers is that learning computer skills requires an extended amount of time before they reach a comfort level and a level of confidence that will enable them to involve their students (Fisher & Dove, 1998). Imagine the plight of the school administrator or supervisor who needs to become sufficiently computer competent to be an integral part of a professional development program in instructional technology. According to McKenzie (1998) the challenge of integrating technology into the instructional program may be more about attitude and spirit than it is about skill. To move instructional technology to a higher plateau administrators and supervisors must become stakeholders and buy into the use of technology as an administrative and instructional tool. To accomplish this, districts and school principals need to devise innovative ways of delivering ongoing professional development that is both flexible and effective.

Implementation of an Online Course for Supervisors

The Principal of a large, urban high school in the northeast instituted a course of study for administrators using Blackboard as the vehicle. The purpose of the course was to train the ten assistant principals in his school in the use and implementation of IT in the classroom. The ultimate goal was for the assistant principals to provide turnkey training for teachers in their own departments. The Principal chose to offer an online course for this professional development because it had the greatest chance for optimal participation by those involved. According to Sujo de Montes and Gonzales (2000) courses that are Web-based provide a viable option for professional development of teachers and administrators.

Although the Principal of the school had a background in computer science and IT, the level of computer competence among the assistant principals varied greatly. While one of the assistant principals was a supervisor of business subjects and author of textbooks and workbooks in various computer applications, two others had little or no experience with computers. The other seven assistant principals were at the same level of minimal competence. Most were infrequent users of e-mail with personal accounts at home. All used word processing software to write letters, memos and observation reports. A few even developed some test banks for different courses within their department.

Each of the ten "learners" had access to the Internet at home and each had a computer in his/her office in school. However, only six had Internet access in their office. Therefore, the first order of business in the beginning of the school year was to provide Internet access for the four assistant principals who were without this tool in their office. Once Internet access was available to each of the assistant principals, both at home and in school, the course of study began.

Following the normal routine of a typical school year, regular bi-weekly administrative cabinet meetings took place. The difference for this school year would be that every other cabinet meeting would include one and one half hours of professional development in an Internet accessible computer lab with the Principal serving as trainer and facilitator. According to Holbein and Jackson (1999) teachers and administrators need both time and support to acquire and sustain computer literacy. Given the regular training schedule, the accessibility of Blackboard, and the expertise and support of two colleagues, the course of study had an excellent chance for success.

The Online Course of Study

The focus of the initial meeting for the training course was to familiarize the supervisors with Blackboard. Supervisors completed the data entry of personal information and were given a guided tour of the Web-based tool. Once familiar with navigating Blackboard, supervisors were given assignments at regular intervals over the course of the fall semester to be completed by the following meeting.

The **Announcements** section of Blackboard was used as a method of conveying information to the assistant principals about new assignments and general feedback regarding previous assignments. The **Course Information** and **Staff Information** sections were used for demonstration purposes, showing the assistant principals how a teacher could readily relay information about an online course to his/her students. The **Course Documents** section contained several documents: the course content, course objectives, and a web site evaluation form.

The **Assignments** section listed all of the assignments up to and including the most current assignment. The first assignment required participants to log onto Blackboard, enter the requested personal information, then use the **Communication** section of Blackboard to e-mail the instructor (Principal) that they got to this point in the assignment. Initially, all participants used their personal e-mail addresses in setting up their Blackboard accounts. Since this was the participants' initial encounter with Blackboard, the instructor used a face-to-face meeting to walk them through the assignment, making sure that they were comfortable with the online classroom tool.

The next feature explored by the group was the **Discussion Board** of the **Communication** section. Teaching this skill early in the course enabled the instructor to create a community of interactive learners. As Brown (1997) points out, online discussion has a number of advantages over oral real time discussion. Learners can respond at a time that best suits them, allowing for reflection and further research before responding. Dutt-Doner and Powers (2000) maintain that while a new instructional tool such as electronic discussion groups can have some stumbling blocks, it can have tremendous impact upon discussion and thought. In addition to giving his supervisors this new instructional tool, the Principal was also able to get feedback regarding school related issues, programs and possible changes in certain school policies. The **Discussion Board** served a dual purpose – it allowed for dialogue among the supervisors and administrators, and at the same time, reinforced the use of the **Discussion Board** as a tool for ongoing communication among all participants for the duration of the training course and after completion of the course.

Since all of the participants were familiar with MS Word and had some experience surfing the Web, much of the training and assignments given utilized this common knowledge as part of an overall assignment. Web-based training and assignments included Web surfing, Web site evaluation using a comprehensive form placed in an MS

Word document on Blackboard and downloaded by the participants, a scavenger hunt using various search engines, simple Web page design using Blackboard, and a "googlewhacking" contest in which participants had to find two words that produced a single hit in a Google search. Other training and assignments included saving a graphic to disk, inserting a graphic into an MS Word document, and attaching a document to an e-mail message.

A slight detour in the course took place when the Board of Education for the school instituted a new Web-based e-mail system using Microsoft Outlook Web Access for all supervisors and teachers in the entire school district. Since all the learners were using their own private e-mail, the group agreed that it would be wise to learn the new system for consistency. The training for the new e-mail system was then done through the online course using Blackboard. A simple user's guide was created by the Principal and the Business Department Assistant Principal, and distributed to the participants via Blackboard. A new set of assignments was created for the group that reinforced such common e-mail tasks as reading a message, replying to a message, forwarding a message, and attaching a document to a message. Other features of Outlook Web Access such as creating folders, setting up a directory of contacts, and creating distribution lists were reviewed in the **Course Documents** section using "How to" sheets and reinforced through the **Assignments** section.

Having used an online method of delivery, the assistant principals shifted to the new system of e-mail with relative ease. Personal information on Blackboard was updated, and all further e-mail correspondence used the new system for reinforcement.

By the end of the fall semester, each of the assistant principals demonstrated skills acquired through the regular submission of assignments. By the beginning of the spring semester, nine of the ten assistant principals were using e-mail on a daily basis. For his part, the Principal made it a point to e-mail the assistant principals each day. This served not only as a method of daily communication, it also served as a way of reinforcing e-mailing skills learned in the online course.

As the group moved into the spring semester, the focus shifted to more advanced uses of computer technology. In doing so, more ambitious training and assignments were implemented during the spring semester. These included such activities as creating a PowerPoint presentation, using Inspiration to create semantic maps, downloading and adapting lesson plans, and creating inquiry-based learning projects. A single face-to-face training session took place for each activity. This was followed by a reinforcing assignment, done independently or collaboratively, and submitted online.

Plans for the end of the spring semester revolved around preparations for the assistant principals to turnkey this training with their teachers in the fall 2002 semester using a similar ongoing, online professional development program with Blackboard as the vehicle of delivery. Department supervisors planned to tailor the supervisors' course to meet the needs of the teachers in their particular academic discipline.

Reflections

According to Schmeltzer (2001) creating a community of learners among the administrators of a school or district is crucial to the success of any professional development program. Throughout the year, the online course provided a mechanism for the school supervisors and administrators to share ideas and skills. By creating such a learning circle, great improvements in teaching quality can be realized (Collay, Dunlap, Enloe & Gagnon, 1998).

A course evaluation was conducted at the end of the school year through the discussion board. Each assistant principal was asked to offer his/her evaluation of the course and to respond to at least one of his/her colleague's evaluations. In general, the assistant principals found the online course to be a very worthwhile endeavor. As one computer novice assistant principal remarked, "The projects required me to use the computer to a much greater extent than I had, something that was necessary for me to see its advantages."

During the fall semester most of the assistant principals reached a comfort level with the technology and developed a better sense of community with one another. Through the use of the discussion board, the learners were also able to share reflections and experiences, frustrations and successes. The administrators and supervisors felt strongly that the social element provided by the online course was as important as the technical and instructional components. As one participant noted, "The discussion board and regular use of e-mail enabled us to maintain ongoing communication, something that was lacking in the past."

The use of regular "face-to-face" meetings was deemed important and necessary by the participants. However, since the meetings were scheduled during the school day, some of the administrators and supervisors had occasional distractions that were somewhat disruptive. It was agreed that, in the future, these "face-to-face" meetings be conducted outside the normal school day, thus limiting unforeseen disruptions.

Conclusions

Comprehensive integration of technology into curriculum and into the classroom will require tremendous vision and effort from our school leadership. As Kavanagh (2001) states, the potential of information technology and the Internet to create communities of learners will continue to have a significant effect on the design of educational programs. School administrators and supervisors need to be trained in ongoing professional development programs that maximize their participation, increase their IT skills, and develop a community of learners and instructional leaders within their schools. Collaboration tools such as *Blackboard* can facilitate the "anytime, anywhere" professional development necessary to accomplish this goal. Other such collaboration tools include *LiveText* by LiveText (www.livetext.com), WebCT by WebCT (www.webct.com), *FirstClass* by Centrinity (www.centrinity.com), and *Polycom WebOffice* by Polycom (www.polycom.com). Since budget limitations can be an issue for many schools, similar ongoing collaborative professional development can also be accomplished through the use of e-mail and attachments.

Whatever the method of delivery, a professional development program that provides opportunities for learning, and is independent of time and location, has the greatest chance for ensuring technology integration into the classroom.

Abstract: The purpose of this project was to investigate the perceptions of instructors and students with regard to delivering effective instruction in synchronous learning environments. The specific research goals were to attain an evaluation of the quality of distance education courses, to determine the effectiveness of the delivery medium, and to examine instructors' and learners' perceptions of the instructional strategies implemented in courses delivered through the medium of real-time audio-video teleconferencing via the North Carolina Information Highway.

Introduction

Distance education programs across the country have been expanded to meet increased needs in higher education. Traditionally these courses have used face-to-face, two-way interactive video, and web-based instruction. Guidance often consists of learning about the use of cameras, PowerPoint, video options, and web boards. Numerous training manuals have been written in this field with a questionable basis in research. Educators need to make sure that technology is not driving the learning experience when there is added pressure to enlarge the number of students in various programs. In addition, educators who understand pedagogy must take the lead in teaching techniques via distance. Before we continue serving students with distance learning we need to answer some essential questions regarding effective teaching in synchronous and asynchronous environments. In search of the answer, the fields of education and technology have studied student perceptions comparing online to traditional lecture class quality (Ryan, 2000), the achievement of students in distance education and traditional classrooms (Schulman & Sims, 1999; Dominguez & Ridley, 1999), demographics of students taking online courses (Guernsey, 1998), staff training needs (Connell, 1998), support for faculty teaching (Bremner, 1998), and community and team formation in distance education classrooms (Berg, 1999) and numerous other subjects. We have also examined traditional versus nontraditional roles for the teacher and new paradigms for on-line learning (Bourne, McMaster, Rieger, & Campbell, 1997; Shneiderman, Borkowski, Alavi, & Norman, 1998). The need still exists to examine the role of the teacher and effective strategies for effective teaching. As Shneiderman (1998) wrote, "technology can be wonderfully empowering for teachers and students, (but) the relationship between human beings is still the heart of the educational process."

BEST COPY AVAILABLE

Purpose

This study attempted to examine the perceptions of teachers and students in distance education classes taught by university faculty from a college of education. Graduate students who were practitioners in various fields of education were the participants in these synchronous classes. It was anticipated that this pool of students would give insight into appropriate and inappropriate uses of various teaching strategies and techniques due to their expertise in education. A web site with a discussion board was created to allow for interactions among students about: 1) the quality of learning, 2) effective teaching strategies, and 3) the effectiveness of the media of course delivery. Four instructors with experience teaching in synchronous learning environments also responded to these questions and their responses were also compiled, analyzed, and compared with student summaries.

Theoretical Framework

The conceptual framework that serves as a philosophical basis for our institution posits that faculty and students come together as a community of inquirers to examine the aims of education and the nature of teaching and learning for achieving worthwhile educational goals. Teaching is viewed as a dynamic, goal-oriented, social activity, and learning is perceived as an active process of acquiring, assessing, and producing knowledge. We collectively embrace the exploration of new forms of teaching and learning through experimenting with emerging technologies. To this effort, we work as a community of practitioners who embrace the social constructivist perspective and encourage discourse from various levels of participants in solving educational problems.

The Study

When the researchers in this study determined a need to engage graduate students in a collaborative effort to evaluate the quality of their learning experiences from courses offered via distance learning, two groups of students were selected. These two groups of students consisted of majors from the field of instructional technology and elementary and middle grades education who were currently employed in their field of expertise. The technology majors were enrolled in the course *Planning for Technology in Education*. It is one of the advanced courses students must complete for a graduate degree and K-12 licensure in instructional technology in North Carolina. The course emphasizes the development of technology plans at local, school, and district levels. In addition, the issues and processes of successful grant writing are explored. This course was taught simultaneously to two groups of students at remote sites and one group on the campus. The remote sites had computers for each student, while the main campus site required students to use a computer lab located in another building. Each site had a technician to assist with the overall operational details of the teleconference. A web-based supplement was also developed for the course that included an orientation, daily outline and assignments, resources and a threaded discussion forum. The instructor for this course had previously taught with this delivery medium. The elementary and middle grades education majors were enrolled in the course *Connecting Learners and Subject Matter*. It is one of the required courses for all education majors for the graduate level degree. The course emphasizes effective strategies for ensuring student mastery of content. This course was taught simultaneously to two groups of students with one group on the main campus and the other section at a site approximately 90 miles away. Each site had a technician who assisted with cameras, sound, equipment, and trouble-shooting when the technology difficulties occurred.

The North Carolina Information Highway (NCIH) program used in this distance learning study provided video teleconferencing capability to universities and public schools across the state. The "Highway" originally established for video communication today serves as the centerpiece of the states high-speed data network, supporting the data, voice, and video needs of all government at the state and local levels as well as school systems and other public entities. Using the high-speed backbone of the

North Carolina Integrated Information Network (NCIN), our NCIH services provide broadband connectivity and setup of on-site video conference rooms to support a host of point-to-point and multi-point conferencing applications, including the distance learning medium used in this study.

Altogether 73 students were enrolled in these two classes. The instructional technology majors were aware of the synchronous learning environment in advance. However, the students enrolled in *Connecting Learners and Subject Matter* were not informed in advance of the delivery system to be used. These students met for a sixteen-week semester and when the courses were complete, they were asked to provide feedback on their pedagogical and technological experiences. These students volunteered to participate in an open-item questionnaire that was designed to collect demographic data and feedback regarding the quality of their learning experiences in these distance education courses versus courses that did not involve this delivery system. Students also analyzed the effectiveness of teaching strategies used in these courses and the effectiveness of the NCIH. The survey was posted on a password protected website and required students to give permission for their comments to be used in a research study. Results were summarized and presented below.

Research Questions

Each graduate student enrolled in these two courses was invited to participate in a research project designed to assess the quality of the delivery system used in their class and to examine their perceptions of the instructional strategies used. The following questions were posted on a password protected website.

1. Contrast the quality of the learning experience in distance education courses versus on campus courses (interaction, instruction, assessment, etc.).
2. What teaching strategies have you found to be effective in distance education courses?
3. How effective was the medium for delivery of the class (ie. NC-REN, NCIH, web-based)?

Altogether 46 students logged onto this website and participated in this research project. Four instructors responded to the survey.

Findings from Students' Responses

In the following narrative, the students' responses to the research questions are summarized. Specific quotes are used to highlight student perceptions.

Question 1

When students were asked to evaluate the courses delivered in synchronous environments using NCIH, the quality of instruction was perceived as high and being "as good or better than courses taken on campus." However, students reported a strong preference for the professor to be at their site and felt that "instructors should be required to spend equal time at the various sites. Students miss a lot by not having direct contact with the instructor." One student wrote, "...the quality of instruction is not diminished by the remoteness of the instructor and learner" and further stated, "We tend to work more cooperatively as a group because of the distance, therefore, depending on one another more." Another student commented, "Distance education is a good tool if all people included work together to make it successful. I don't believe it can be successful when the groups are looked upon as separate entities. We must be a whole."

Several respondents commented on the limitations of distance education courses. "The frustrations of the technological problems... made this class difficult and often non-productive," wrote one student. Statements such as the following were posted. "A few glitches occurred with the delivery because of the equipment." "Time was wasted due to technical difficulties." "As technology bugs are worked out, distance learning should improve." These comments appear in the final research question as well.

In summation, while students prefer direct instruction with the professor, many would not have been able to obtain a graduate degree due to living a distance from the university campus. The convenience of this delivery medium has "truly benefited" the majority of students.

Question 2

Graduate students were asked to reflect on the effectiveness of the strategies used in distance education courses. The majority of students commented that small group discussions and cooperative learning activities were the most "effective strategies used by the professor." One student stated, "I believe that small groups discussing the topics and then coming together as a whole is the best strategy I have used." This use of instructional time allows students to "get things accomplished without the hassle if technological problems." Another stated, "Small group discussions kept the program personal and relevant." "The instructors were adept at encouraging students to pursue areas of interest."

One student commented, "Just like in a regular classroom, variety is key: Cooperative Learning, Videos, Power Point, Direct Instruction (providing that the technology is working). For two sites, it is effective to bounce questions back and forth so that you can get everyone involved and sharing." "Power point and the overhead were good to supplement direct instruction" because visual learners need additional support. Literature circles used in the *Connecting Learners and Subject Matter* class was cited as a "very effective strategy" also.

Least preferred by students were lectures and large group discussions. For example, "whole group discussion was limited to the technological difficulties" of having cameras and sound focused on the speakers.

Question 3

Determining the effectiveness of the NCIH delivery system was the purpose of the third question in this survey. Students enrolled in *Connecting Learners and Subject Matter* reported more frustrations with the delivery medium than their counterparts in the *Planning for Technology in Education* course. Technical difficulties such as "...voice delays, freeze frames, and just being down were common to our classes this term." Most students made comments such as the "...the NCIH was not successful in truly making the class a good learning atmosphere." "I know that the technical folks here worked really hard; however, we have experienced technical problems," and "NCIH has a lot of room for improvement."

To the contrary, students enrolled in the technology course said, "NCIH has worked well. We've only had a few instances when connections did not work. The biggest problem was that voices broke down often and at times the volume from campus was very low." One student reported that this delivery system had been used frequently and they had learned the value of flexibility." However, one of thee students questioned the amount of money the state invested in this technology saying, "It would be better to just have web-based courses." Another concluded that though there were technical problems, they far outweighed the safety concerns of having to drive 60 miles at night through winter weather, and the fee was affordable."

In summary, both groups of students see NCIH as a good idea that will continue to be a part of graduate level education.

Findings from Instructors' Responses

Each of the authors in this project has had experience teaching in synchronous learning environments. When queried, each gave responses to the survey questions posed to the students enrolled in these two graduate level courses. Examples of summarized responses are included to provide insight from their perspectives.

Question 1

When instructors were asked to contrast the quality of the learning experience in distance education courses versus on campus courses, the following comments were dicited. "When I create a course for students, I begin with a philosophical stance and an examination of the goals and objectives for the course. Then I consider the delivery medium, as in the case of face-to-face instruction versus satellite delivery of content. My goal is to maintain the quality of instruction in each learning environment and to ensure that each student masters the content of the course with a high level of satisfaction." "I taught an off-campus introductory course with undergraduate students enrolled in an elementary education cohort. These students were adult learners juggling family responsibilities, full-time jobs and two evening courses over a fall semester. As an instructor, I am committed to incorporating social constructivist teaching methods into the teaching and learning of a course. It was my goal to deliver this course via satellite with the same quality as an on-campus course." Another instructor made this comment. "I have taught campus based face-to-face, remote synchronous audio/video conferencing based courses (both site-to-site and site-to-multi-site). Learning on campus or delivered at a distance must retain the same high qualities expected of adult graduate education. Regardless of delivery systems used, one would expect students to become independent learners, to explore ideas beyond their usual comfort levels, and to develop practical meanings and applications from their studies. Face-to-face communication enables an instructor to continually monitor the nuances and progress of individuals and groups toward these goals. Using distance delivery systems, the instructor must develop new ways of assessing progress. This includes giving up much of the local 'control' associated with traditional teaching. It also requires a strong emphasis on the student's responsibility for learning. Using distance modes of delivery has not diminished the quality of student learning as measured by the stated goals; however, these goals may differ from those associated with more traditional instruction." The fourth response follows. "My initial thought on the quality of the learning experience in distance education courses was that these classrooms were inferior to traditional face-to-face teaching situations. As a teacher who enjoys a lot of communication, physical movement, and group interaction in classrooms, it was hard to look past the model of the talking head in distance education. At first, I felt like a news reporter that should stay in one place and restrict movement After several weeks, I became more comfortable with the new environment and realized that the surroundings could be adjusted for effective learning. At this time I retreated to my knowledge base of good teaching and used effective strategies that have worked in other learning settings."

Question 2

Instructors' perceptions of teaching strategies found to be effective in distance education courses via satellite are summarized here. "I believe 'best practice' requires the use of effective research proven strategies and that requires a socio-constructivist bent as is articulated in the conceptual framework which guides the practices of our faculty. As a result, I strive to create a classroom that is characterized by a community of learners who collectively and collaboratively solve problems and engage in activities designed to enhance their understandings of subject matter. Specific strategies include small cooperative group assignments, presentations, and discussions, as well as guest speakers, lectures, PowerPoint presentations and videos. The underlying goal is to engage students in constructing their own understandings of subject matter." "I used small group cooperative learning activities, web board discussions, and literature circles in addition to discussions and presentations with this class. I made the decision to travel to the class site every other week and to conduct the class via NCIH on alternate weeks. I did this because I believe the richness and immediacy of face-to-face communication was needed with this particular group of students." "Teaching strategies that seem to enhance my distance education courses include interactive websites, assignments which guide but not direct, group interaction, executive summaries, projects, and guest speakers." "Direct instruction and lecture were effective if I kept thoughts concise and frequently interjected student comments, video examples, and other visuals. Group discussions and cooperative learning were initially difficult for me because I felt the need to closely monitor the groups. Presentations that allowed the students to experience communication through a synchronous environment were highly successful."

Question 3

The question regarding the effectiveness of the medium for delivery of the class (ie. NC-REN, NCIH) received the following reactions. "As long as the cameras, sound equipment, and the links to remote sites were working correctly, my instructional goals were met. However, on days when the technology support

BEST COPY AVAILABLE

personnel had difficulty with the equipment, delays occurred, and learning goals were not met. It became clear that the greatest barrier to effective teaching via synchronous delivery systems was a medium that did not work!" "I found that the time delay in the two-way interactive video transmission hindered class understanding and learning. Discussion was very important in order to teach and learn concepts. It was impossible to maintain the affective elements of a discussion, particularly maintaining eye contact, reading body language, and conveying non-verbal messages via the two-way interactive video medium. I subsequently ended the NCIH and traveled to the site weekly for class. The web-assisted medium of the web board discussions worked very well. Students learned how to use a piece of technology, could complete the assignment at a time convenient for them (asynchronous), and participated in a small community of learners. The students worked in this same team during class time and the carry over from class to the web board was very effective. In conclusion, I believe the two-way interactive video is dependent upon factors out of the instructor's control, such as bandwidth allotted for the transmission, skill of technicians assigned to the class, and the learning needs of student populations. As such, the quality of instruction is variable. The web board, in my experience, was an excellent teaching and learning tool." "In my experience, each distance delivery medium has capabilities that emphasize different aspects of learning. One of the greatest challenges for each mode of distance education is how to best engage students in conversations with each other. The available technology may enhance or diminish these communications. I have found, for instance, that in using synchronous audio/video, it was difficult to meaningfully engage small groups at each of the multi-sites and provide them with opportunities to share their work at other sites. The non-dependability of the synchronous environments require that each site had access to the web for each session so that students could work independently if the technology failed. Another great challenge is to switch from being a dispenses of knowledge to being a guide – and trusting students to take responsibility for their own learning." "Technological problems hindered my class and affected the effectiveness of learning. On several occasions I did not have the necessary support to change camera angles, switch to PowerPoint, or watch videos. There was not a good working relationship between the technical staff and the instructor. (Staff usually consisted of students who were often replaced during the semester and sometimes during the class period.) The technical problems between two sites also ranged from delayed audio and visuals to complete disconnection. All of these problems were very frustrating and prompted me to begin driving between the two sites on alternative weeks. When I teach in a synchronous environment again, I will also create a web to assist the class with assignments and to create another method for interactions. This medium was highly effective when I asked a colleague to help teach at the second site. He kept students performing at one setting while I was teaching and interacting at the other."

Discussion

Teaching is a complicated task even in the most favorable of conditions. Teaching and learning in a nontraditional environment requires both the teacher and learner to modify how they interact. The instructional strategies employed in distance programs must be examined from the perspective of the learner and the instructor. Instructors must be apprised of specific guidance based on research. By analyzing the perceptions of classroom teachers and instructors in their roles as students, we can delineate good from poor practice. Studies such as this offer much insight into the pedagogical issues that accompany the integration of new forms of technology.

Cognitive user profile and its involvement into adaptive interface

Laboratoire ICTT
Leonard de VINCI 21 Avenue Jean Capelle
INSA de Lyon
69211 Villeurbanne Cedex - FRANCE
E-mail: {habieb, tarpin}@ictthp.insa-lyon.fr

ABSTRACT

An adaptation technique of multimodal interfaces based on a cognitive modeling of users is presented this paper. The adaptation process tries to select a combination of modalities that best fit the cognitive profile of each user. This profile contains indicators of cognitive abilities and styles. Today, we focus our attention on output modalities and apply our technique on hypermedia documents. The system we here present is implemented using the XML and ASP technologies.

KEYWORDS: adaptive interface, user modeling, XML document.

INTRODUCTION

Researches on adaptive interfaces and user modeling have attracted attention over a decade ago and seems to have recently aroused a renewal of interest, mainly thanks to hypermedia. As the amount of on-line information grows at an astonishing speed, people feel overwhelmed by the information currently available, and the corresponding media landscape [Elting, 2002]. This clearly leads to a need of automated methods, commonly referred to as adaptive interfaces, that present information with respect to the user's profile. As adaptive interfaces aim at automatically adapting to individual users, the development of appropriate user modeling techniques is of great importance. Techniques dealing with user profile construction are drawn from work from cognitive psychology and human computer interface.

We first describe the supervised cognitive training program called HAPPYneuron™. This program enables the construction of the cognitive profile of users. We then investigate adaptive techniques using this profile. We focus our first work on output modalities in the context of hypermedia. We have chosen XML and ASP technologies to implement the system. Evaluation tests are in progress.

'HAPPYNEURON' SITE DESCRIPTION

In collaboration with the SBT society, we have worked on an interactive web site proposing a supervised cognitive training: www.happyneuron.com [Tarpin-Bernard, 2001]. Mainly dedicated to seniors, this web site provides exercises that train and evaluate cognitive abilities. During each training session (i.e. each connection), the user performs a set of exercises suggested by the system. Presented in a playful and cultural dimension, exercises vary in difficulty level, speed... in order to entertain the user [Habieb-Mammar, 2001].

Normalized data is stored into a database (means and standard deviations) for each variant of exercise and family of population distinguishing gender, educational level and age [Tarpin-Bernard, 2001]. Current statistics show that since the web site was open to the public (summer 2001), the number of performed exercises exceeds 600.000 and the population of players is well distributed between 15 and 80 years of age. Comparing the trainee's results and normalized data, we are able to progressively build the user cognitive profile. It then enables the system to advise the user in his choice of exercises.

In this context, we have built an evaluation module composed of ten precise exercises that enables to quickly build a cognitive profile. Then, this profile, which is quite stable, can be used in very different contexts. Our first purpose is to elaborate an adaptive multimedia course on the brain. Depending on one's profile, the lesson will be presented using the most adapted media.

Before describing the adaptation process module, we may start with the definition of these cognitive styles.

WHAT ARE COGNITIVE STYLES ?

Cognitive styles refer to a person's usual, prevalent, or preferred mode of perceiving, memorizing, learning, judging, decision-making, problem-solving [Dufresne, 1997].

Individual differences about how people carry out tasks involving these functions may constitute a style if they appear to be: pervasive, which means that they consistently emerge in different contexts, independently of the particular features of situation; or stable, that is, they are always the same at different times.

BEST COPY AVAILAB

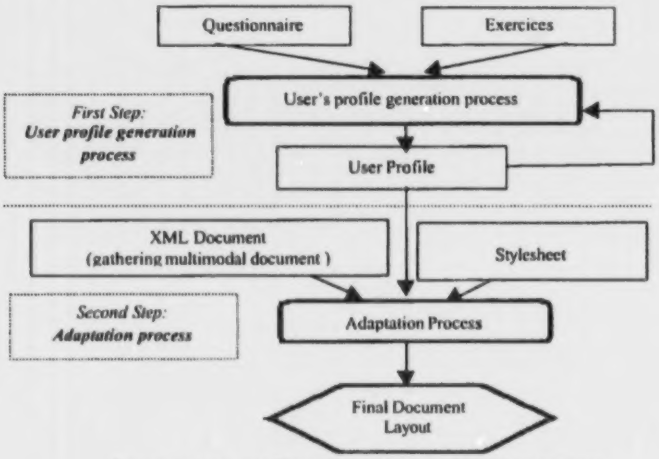
They are one of the most stable user characteristics overtime. They are consistent across a variety of situations, as opposed to user knowledge or experience that is more specific and evolving. Numerous studies have shown the importance of cognitive styles in the area of HCI research and their implication in the design of the interface [Muylwijk,1983].

Cognitive styles induce people to adopt similar attitudes and behaviors in a variety of domains concerned [Daniels, 1996]. Cognitive styles are important in determining the most effective interface for a particular category of user, especially in the formative stages of an interaction [Fowler, 1985].

They can be conceptualized as a cross-road of thinking, personality, and motivation. In fact they concern the kind of strategies an individual tends to apply when faced to a situation or to the preferred way of processing information.

OUR APPROACH

The two important steps adopted in our approach are structured as follows (figure 1) :



Questionnaire
Exercices
User's profile generation process
First Step: User profile generation process
User Profile
XML Document (gathering multimodal document)
Stylesheet
Second Step: Adaptation process
Adaptation Process
Final Document Layout

Figure 1: User profile generation and adaptation process

The user's profile generation process consists in executing a sequence of interactive exercises then computing the cognitive profile.

The main components of the output profile are:

1- Cognitive indicators dispatched into 5 sectors: *memory, attention, executive functions, language and visual & spatial capacities* [Tarpin-Bernard, 2001]. In detail, 25 indicators have been determined. We can mention several of them as an illustration: cultural memory, recent memory (verbal, visual or musical), working memory, lexical spelling, categorization, comprehension, planning, reasoning, form recognition, etc ;

2- Styles indicators revealing some cognitive styles such as field dependence. These indicators are determined combinating cognitive indicators or through the comparison of the results obtained in several exercises. For example to determine whether the subject is field dependent or not, we use an indicator which measures the difference in performance after running the same exercise with two different images (the first with significant context and the second with non-significant context) then we adjust it with other cognitive indicators such as recent memory (verbal, visual or musical) and comprehension.

Using the cognitive indicators, we have modeled the cognitive sectors that are most solicited while performing an exercise. However, in practice, an exercise cannot imply a unique sector. Every cognitive activity results from a parallel or hierarchical processing of a lot of cognitive abilities. For each exercise, we have determined the different solicited indicators and chosen weight factors ($0 \le p_i \le 10$). After each exercise running, the performance (P) of the user is computed using the average performance (M) and the standard deviation (σ) of this performance that are stored in our database and result from other users which have the same characteristics (age, gender and level of education). A user with an average performance will obtain a score of 50 (the default value)

BEST COPY AVAILABLE

and someone with a very good performance of M+2σ will obtain 90 (2,5 % of the population) [Habieb-Mammar, 2001][Tarpin-Bernard, 2001].

This user profile enables the selection of outcome modalities. The multimodal document is defined into an XML document. We here consider the three main modalities: text, image (picture, diagram, video) and sound (music, jingle or voice). Prior to any process, the stylesheet contains the layout of the complete page to be presented. For a specific subject, the final layout of this page is brought through the adaptation process which is mainly a filtering process. According to us, this layout is the most compatible with the user cognitive profile.

To illustrate the adaptation process, we hereafter give an example of a page dealing with the *Memory* item. This page presents two sub-items : "definition of memory" and "mechanism of memory". In the XML document, the page falls under 2 elements. Each one may be presented according to different modalities. *TR* and *TC* stand for Reduced and Complete Textual elements of a page. *IR* and *IC* refer to Image modalities (Reduced and Complete) and *RV* corresponds to a Recorded Voice that explains a concept (figure 2).

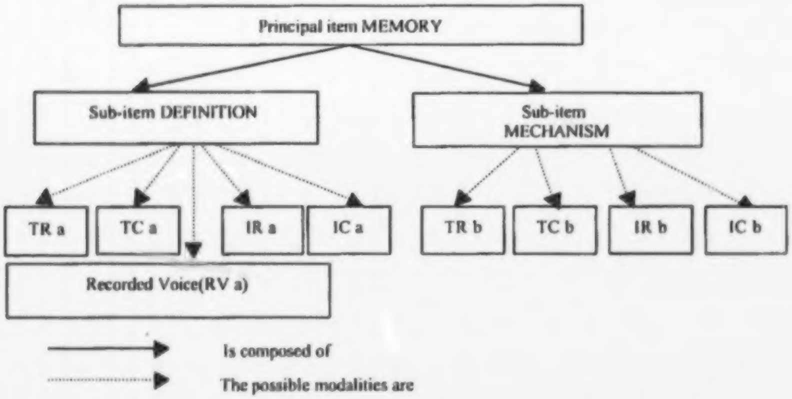


Figure 2: XML document structure

The issue is to find the "best" combination of modalities according to the will of the designer and the abilities of the reader. According to the XML structure, the possible combinations are: (*TRa*, *TCb*), (*TCa*, *IRb*), (*TRa*, R*Va*, *TCb*), etc.

On the other hand, we build a compatibility matrix whose lines correspond to criteria extracted from the user profile components (cognitive styles and interaction styles) and whose rows are the possible combinations of modalities.

For each combination and each criteria (e.g. capacity to manage of multimodality, respect of preferred modality, field-dependency...) a compatibility factor is calculated using an arithmetic formula that combines the user's profile and the characteristics of the combination. The combination of modalities that results in the biggest sum is considered as the most compatible one.

Indeed, An ASP program on the server side builds an enriched XML document that contains the whole page to be presented. Each part, which is presented as a tag, has an attribute called *etat* (*state)*. This attribute may hold the values 1 or 2, where 1 corresponds to the reduced form of the output modality and 2 is the full form. Thanks to the user profile and the items priority (i.e. the important items which have to be shown), the ASP program include the state values into each (figure 3).

CONCLUSION

In this paper, we have described how to generate and then incorporate the cognitive profile into adaptive multimodal interfaces. The first step consists in building the user cognitive model through a set of interactive exercises. Based on demographic data, this model combines 2 different types of information: cognitive indicators and style indicators. This profile is the input of the last step of the adaptation process, where the couples (indicators, multimodal combinations) are evaluated with weighting factors. These factors enable to select the most compatible output documents.

As we know that it can be very dangerous to completely rely on our adaptation process, the most compatible items are presented and the less compatible ones can be shown as catchwords using auditory and iconic information. The user can have more information by clicking on these elements. Indeed, additionally situations where spoken and written text deliver non-redundant information could be of interest [Elting, 2002]. An extension of our work will be to learn of these kinds of behaviours, which can induce that our profile has to be corrected.

The first working track has been defined, experimentation and validation work are currently in progress especially to determine the compatibility factors. However, we are leading experimentation upon a population of 50 users to validate the cognitive profile generation process. The aim is to construct a reliable user profile in order to exploit it not only in our site but other coming applications. To evaluate the adaptation process, we are going to compare the amount of learned information between several populations confronted to different presentations of our course. This experimentation, planed in 2002 summer, will be done on HAPPYneuron's users grouped according to their profile. Adapted presentations and non adapted presentations will be proposed and results will be compared. Results will be presented to the conference.

According to theories guide-lines and to our preliminary work we can say that this research field will be promising and fertile with new developments. All this work has been possible by adopting multidisciplinary approach i.e. computer science, cognitive psychology and neuro-psychology.

Adapting Corporate Portal Technology for Management E-Learning

Michael D. Hamlin, Charla Griffy-Brown
Graziadio School of Business and Management
Pepperdine University
Malibu, California, USA
mhamlin@pepperdine.edu

Abstract As the largest provider of MBA talent in the Western United States the Graziadio School of Business and Management had a need to create a technology infrastructure to support students and staff distributed in 7 educational centers throughout California. This paper will describe the process by which the School came to recognize the potential for portal technology to foster communication, improve the quality of service, and enhance the learning experience and will explain how we created a vision for a new collaborative learning and administrative environment. It will also describe how we adapted and deployed real-world corporate portal technology to enhance executive and management education through E-Learning. The School's process for adapting portal technology for E-Learning and knowledge management to create a collaborative learning and working environment has implications and should be of interest to those in higher education and corporate/management training.

Physical Environment: Distributed Students and Faculty

As the largest provider of MBA talent in the Western United States the Graziadio School of Business and Management had a need to create a technology infrastructure to support its 2000+ students and staff distributed in 7 educational centers throughout California. With only a small full-time program at our Malibu campus, the majority of students were working adults attending night-time classes at one of our seven educational centers in Southern and Northern California. Students would often identify with a center or a program but often felt disassociated from the Graziadio School. Faculty were distributed as well often teaching at 3 different educational centers.

Administrative Environment

As is often the case, the School administration saw a general need for an improved information technology infrastructure to tie together students, staff and faculty. There was a general feeling that information technology could be useful to:

- Extend the reach and scope of the Graziadio School business model
- Prepare students to be effective professionals in a knowledge economy
- Use technology to enable the School to "run like a business."

However, the School did not have a large information technology staff nor much experience in technology use or planning. School administration turned to an outside consultant, PriceWaterhouseCoopers (PwC) to guide the development of a technology action plan. PwC helped the School form a Steering Committee and create a process to develop a technology plan to better define the School's technology goals. PwC along with the Steering Committee developed a technology planning Roadmap to guide the design of a new information technology infrastructure for the School.

IT Vision	IT Infrastructure	IT Action Plan
Create a vision for School information technology	Assess existing IT infrastructure including Hardware, systems, software, and networks	Develop recommendations and define initiatives
Agree on guiding principles that will be used to prioritize investments	Integrate best practices	Develop rationale
Identify role for technology and the School's technology goals	Analyze gap between current and desired state	Develop implementation plan
	Design future IT infrastructure model that will allow for future growth	
	Develop cost estimates for hardware, software, maintenance, and implementation	

IT RoadMap

Once the Steering Committee had the RoadMap it could proceed to focus the School's technology goals. The Steering Committee first developed a vision for information technology in management education that was driven by the following premises:

> In the future, management education could be divided into two types of educational providers:
>
> 1. Mass produced, automated, online learning. This learning will be convenient and low-cost. It will be offered to a large number of people.
> 2. Premium quality, personalized learning. This type of learning will be "high-touch." It will also be high-tech, full-service, time-efficient, and relatively high-cost. Small classes and a low student-faculty ratio will enable personalized education.
>
> Straddling these two types will be difficult and dangerous. Pepperdine aspires to be in the second category and must develop a technical infrastructure to maintain -- and enhance -- the quality of its education.

Vision

Built as it was on small classes and individualized attention to student needs, the School was interested in creating a vision that supported its student-centered orientation. The following technology vision was developed based on the School's emphasis on responsiveness to students needs and a desire to improve service and communication.

> The Graziadio School values personal interaction. The School also recognizes the potential for technology to foster communication, improve the quality of service, and enhance the learning experience. Technology should not be embraced for its own sake; technology usage should support the institution's mission and strategic goals.

Desired Benefits

A technology vision is still on a general level so the committee proceeded to focus in on desired goals and objectives to help drive the development of a new information infrastructure. The next step involved the definition of guiding principles and objectives for a successful system implementation. Always mindful that the new system sould be supportive of the school's mission and business goals the committee determined that a system should accomplish the following objectives:

- eliminate redundancy and create synergies between the School and the University

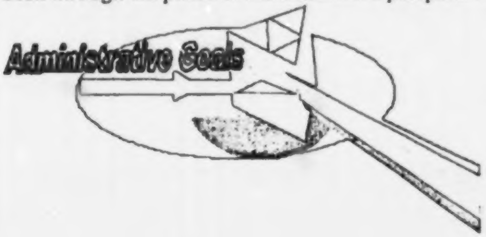
- enable the School to operate more "like a business" through the application of technology that enables increased customer service and the cost-effective administration of the School.
- expand learning and teaching opportunities and effectiveness
- foster a learning environment that is current and relevant to today's business community

Along with these objectives,the committee established some general priniciples to guide the development of the new system:

- User-friendly solutions -- Technology solutions must be user-friendly and rapidly adopted by students and faculty.
- Avoid "bleeding edge" technology -- Although exciting, new technologies are often costly and unreliable. Moreover, supporting new technologies is challenging, particularly given the unique characteristics of GSBM end-users.
- Immediate implementation -- The School is eager to make progress on its technology infrastructure and wants to begin the next phase of this project immediately
- Affordable -- The School has limited resources and must find cost-effective solutions

Administrative Perspective

Seen through the prism of administrative perspective the goals for the system were:

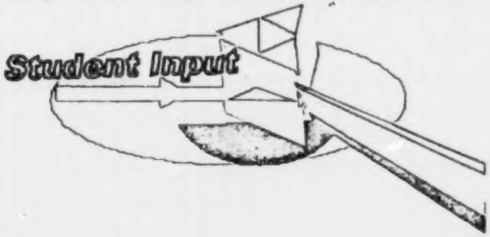


- Extend the reach and scope of the Graziadio School business model,
- Prepare students to be effective professionals in a knowledge economy
- Use technology to enable the School to "run like a business."
- Supportive of the institution's mission and business goals

Needs Analysis

PwC and the School, aware that there any successful system implementation is dependent on user acceptance strove to uncover the needs and perspectives of the potential users of the system. An extensive schedule of interviews, focus groups and surveys was outlined and all major stakeholder groups were consulted to determine how a new technology infrastructure should support the work of the various groups.

Interviews and focus groups conducted with students were quite enlightening and uncovered some interesting insights. See through the student prism, the system would need to address the following:



- Existing technology does not support the learning experience
- Personal service but increased electronic access to information and better access to technology tools.
- Strengthen ability to communicate and collaborate

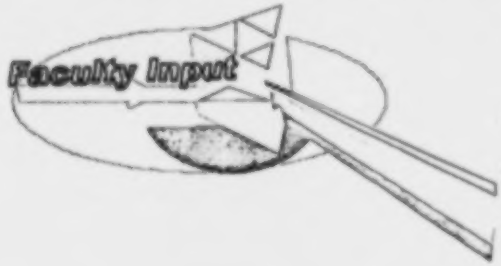
Faculty of course had a different set of perceptions about technology. Because many faculty did not have a lot of experience with technology the committee set out to get a general feeling for what the faculty valued

BEST COPY AVAILABLE

about the teaching and learning environment at Pepperdine. The faculty felt that any new technology should support the traditional strengths of the Graziadio teaching program including these core values:

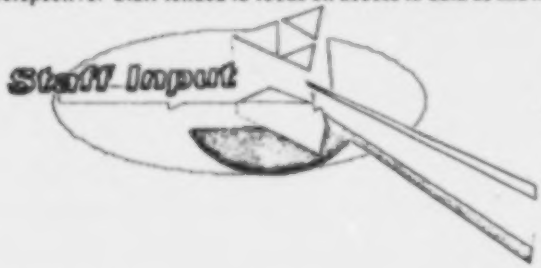
- The freedom and ability to create and re-formulate classes as the situation and opportunity dictates
- Real-world orientation of teaching
- Continued face-to-face contact and small classes.
- Personal contact with students and availability of individualized attention

Seen through the perspective of the faculty the system would support the following



- Support team process and increase collaboration outside class.
- Improve connectivity of students to course-related material, to instructors and other students and provide access to an expanded resource base.
- Provide access to systems that are similar to those used in "real world" businesses.

Polling students and faculty was enlightening and helped focus development of the new system. It became clear that what started out as a desire to improve information technology generally had expanded to become a system that supported teaching, administrative and collaborative activities. Each set of needs can be pictured as being reflected through a different prism Interviews with staff produced yet a different perspective. Staff tended to focus on access to data as shown by the following



- Administrative support is highly dependent on University level services, policies, systems and resources.
- Staff are hindered by manual processes, distributed database development, distributed maintenance, and inadequate storage procedures Data are dispersed among multiple data

Proceeding from the general business process goals defined by the administration further analysis by PwC and the Steering Committee determined that the desired system would have to be very flexible and extensible. A final reduction of the various stakeholders' perspectives produced the following list of objectives the system would have to meet:

- Alignment of technology with business goals
- Access to integrated information
- Ability to communicate, collaborate, and work from any location
- Access to and proficiency in technology tools
- Ability for administration to provide cost-effective, high-quality service

Solution: Corporate Portal Technology

The School looked at a number of different platforms for learning including WebCt, Campus Pipeline and StudyNet as well as communications platforms like FirstClass. Eventually if became clear that none of these platforms could support a majority of needs. One criteria that had climbed to the top of the needs analysis was that the system should allow students to receive hands-on experience with a system that is actually used in corporate America. There was a real desire on the part of faculty and administration that the system be a

BEST COPY AVAILABLE

business-world technology in keeping with the GraziadioSchool's focus on real-world business applications. Eventually we received three responses, one from Oracle, one from Microsoft Consulting Services and one from a systems integration company, Spectria who proposed to link a corporate portal product from Plumtree Software with a collaborational piece called eRoom.

A corporate portal brings together under a standard web-based interface content, applications and services from incompatible platforms, for students, faculty and staff. It is a single point of access to:

- Enterprise applications
- Documents and Web pages
- Internet services
- Collaboration Tools

GraziadioNet Portal Implementation

The GraziadioNet is an implementation of corporate portal technology designed to meet the needs of students, staff and faculty in the areas of education, administration and support.

GraziadioNet Portal "Homepage"

Portals Fill Multiple Needs

From the School's extensive needs analysis it was clear that we needed a flexible tool that could handle:

- Knowledge management and access to multiple sources of information
- Links to eLearning and class content
- Class administration
- Consolidation of multiple information tools such as e-mail and calendars

Fulfilling Many Functional Needs

Seen through the prisms of the various user groups the system requirements became quite extensive. It should be remembered that a high premium was placed on any system that was a real-world corporate solution, could help students better identify with the School, could consolidate multiple information sources and help students, faculty and staff collaborate. As well, faculty were strongly desirous of a system that could support student team projects and increase connectivity among students and faculty. The corporate portal platform which allowed linkages to collaboration software proved to be a real-world corporate tool that could meet administrative needs to automate more of the school's business functions and still serve as a learning platform for students.

Multiple Information Sources

The GraziadioNet Business Education Portal as it came to be called recognizes users as students, staff or faculty and takes them to an individualized portal home page upon logging in. The web-based system can be accessed from any computer linked to the Internet. The individualized home page contains information resources called "gadgets" that allow access to multiple forms of information. Two of the more useful gadgets are the Library and Course eRoom gadgets. The Library gadget provides single-login linkage to a number of business databases such as Lexis-Nexus and Dow Jones Interactive.

Learning Networks: A Proven Approach for Delivering Massively Scalable Blended Learning Solutions

John Harris
Director of Technology
Sapient Corporation
jharris@sapient.com

Peter Cundall
Director of Business Consulting
Sapient Corporation
pcundall@sapient.com

Abstract: Learning networks are a proven way to deliver massively scalable blended learning solutions that have been successfully implemented in a variety of commercial situations. For learning challenges that involve educating hundreds of thousands of distributed learners across thousands of organizations, learning networks can enable the delivery of up-to-the-minute learning content in a blended learning environment for a fraction of the cost of traditional methods. While the challenges of large-scale learning vary depending on the context and subject matter, a variety of common best practices from various implementations of learning networks can be applied to many situations. Any organization seeking a cost effective, scalable, geographically dispersed blended learning solution should consider the learning network approach.

What is a Learning Network?

Learning networks are a cost effective way of delivering learning solutions to large, distributed target audiences. They are highly scalable with no effective upper size limit. Typical examples have thousands of training centers structured in a network of collaborating organizations. These networks typically support thousands of instructors and hundreds of thousands of students. Learning networks often deliver many related courses and some have produced millions of certified alumni. The cost of education in a learning network is usually shared across the entire network of participating organizations and this encourages collaboration between institutions. This type of network has been tried and tested. Many highly effective examples serving various industries and fields of interest exist. They are made significantly more effective when combined with a blended learning approach that utilizes the Internet to deliver instructional material, assessments, communication, and community support tools. Learning networks are not a universal panacea for scaling learning solutions. Some subject matters do not require a blended approach or are otherwise not suitable for learning networks

Scalability and Technology

Many existing learning networks have undergone remarkably rapid growth and now successfully support large numbers of students often distributed around the world. In most cases they have achieved this growth without the significant use of digital technologies. A few networks have recently been built based on digital technologies and these examples show significant improvements over traditional methods. When combined with digital technologies, learning networks offer a compelling approach to delivering massively scalable blended learning solutions.

Scaling blended learning solutions requires all aspects of the solution to be scaled, not just the technology used to deliver content. Many people performing different roles are fundamental to the success of such solutions. Students, teachers, instructors, mentors, and administrators must all participate in the solution. In addition, the solution must be scalable with respect to content development and delivery, instructional practices, and community. These aspects of scaling learning solutions are best solved by an organizational approach supported by technology. They cannot be solved by technology alone.

Typical Features of a Learning Network

Centers of Instruction and a Clearly Defined Theme

Instruction delivered within learning networks usually falls within a narrowly defined theme. This theme usually includes both cognitive and manual skills. The use of specialist equipment is common and the initial learning curve is often extremely steep, requiring students to apply new cognitive and manual skills while using unfamiliar equipment. All these features combine to necessitate the existence of instruction centers that house equipment and provide a place where students can go for initial instruction under close guidance. Mastering the content and skills taught within learning networks often requires a significant amount of study and practice. As a result, the instruction centers often become a focal point for community by bringing both novice and experienced learners together in a collegial atmosphere.

Highly Structured Progression of Courses Leading to Formal Assessment and Certification

Learning networks typically provide a clearly defined learning path for students. A progression of courses from beginner through intermediate and advanced lays out a path that all students must follow. Students can only progress to the next stage following completion of a course and the successful completion of the associated assessment. Once the student reaches the intermediate level, a series of optional, specialized, supplemental courses is available for enthusiastic or precocious learners. Assessment and certification are an integral part of learning networks. Certifications gained within learning networks often have meaning and value outside the network. They can help with employment and sometimes reduce the cost of products and services. In some cases the assessment leading to certification is carried out by a third-party organization, such as a government agency.

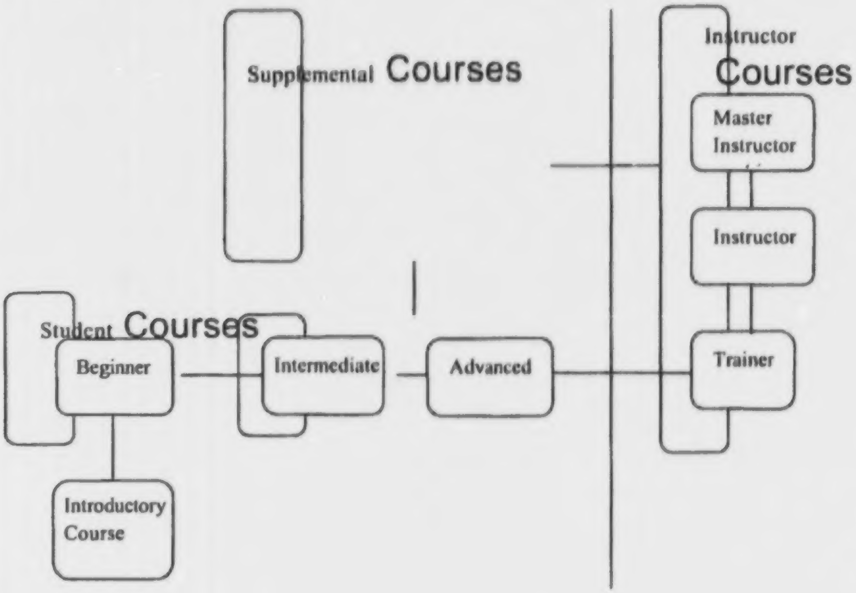

Figure 1: Typical Structure of Courses Offered in a Learning Network

BEST COPY AVAILABLE

Integrated Instructor Training

Most learning networks provide at least two course programs, one for students and a second—available only to those who have completed the advanced courses—for instructors. It is common for learning networks to require instructors to have completed the network's own instructor training course prior to teaching the program's material. Similar to the courses available to students, instructor courses are arranged in a clearly defined learning path. Instructors can, if they wish, progress to be advanced and even master instructors. Instructors commonly earn their living from instructing within the learning network whereas students, even advanced students, do not. Instructor training courses often include administration training for running a participating organization.

A Central Management Agency

A central agency that sets direction and defines curriculum, assessment, and quality standards and ensures overall program consistency is a typical component of learning networks. Agencies of this type are often created initially to serve the needs of the instructor community—only later do they become the central hub of a learning network. In cases where the agency is established by some other organization that seeks to "own" the network, maximum effectiveness can only be realized if the central agency leaves enough "on the table" to keep the instructors involved and motivated. This may be accomplished through financial incentives or the ability to control or customize the program. The central management agency is never run for a significant (if any) profit. Instead, the network is run for the benefit of the member organizations, instructors, and students. The financial value generated by successful learning networks is spread throughout the entire network, not concentrated in the central managing agency.

A Network of Ranked Collaborating Organizations

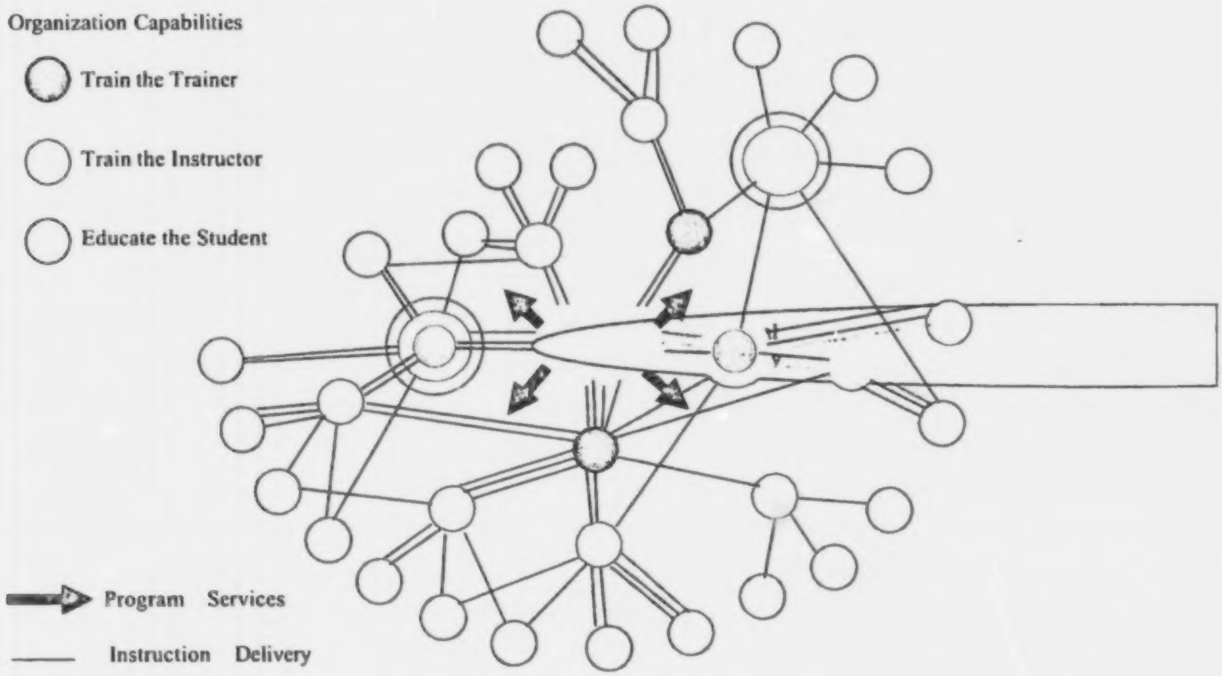

Figure 2: A Schematic Representation of a Learning Network

The organizations that comprise a learning network are typically ranked based on their capabilities within the program (for example, one- to five-star academies). These rankings are determined by the proficiency of the instructors an organization employs as well as the facilities and equipment it possesses. The rank of an organization determines the type of courses it is allowed to offer within the program. Usually, this rank determines the highest level of student the organization is allowed to certify. For example, a one-star academy can certify students in the basic, intermediate, and advanced courses; a two-star academy can certify trainers; and a three-star academy can certify instructors that train trainers. To advance within the program, an organization must increase the proficiency of the instructors it employs. This can be done by sending instructors to other, higher ranked academies for training. This train-the-trainer model leads to the development of a hierarchy within the network. Higher ranked organizations are required to recruit and grow less capable organizations. These features combine to drive the growth of learning networks and self regulate the network—whereas poor-quality organizations tend not to grow

Quality Assurance Program

A formal process for removing low-quality instructors and organizations from the program is typical of many learning networks. This process is usually provided by the central management agency and takes the form of a quality program for collecting and investigating complaints.

The Anatomy of a Learning Network

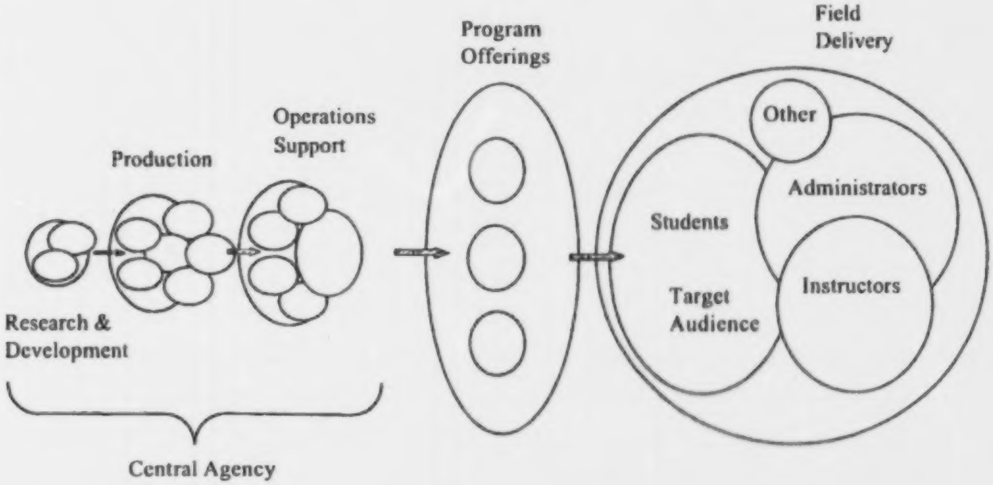

Figure 3: Functional Components of a Learning Network

The Production Line Analogy

Learning networks are analogous to typical product manufacturing production lines. Many of the rigorous business processes developed for product manufacturing can be beneficially applied to learning networks. The central management agency of a learning network is responsible for "manufacturing" and "bringing to market" programs of instruction. These programs usually contain multiple courses and are delivered into the field by the "distribution network" of organizations that provide instruction to students. Many of the disciplines of product manufacturing can be applied. Launching new programs is analogous to launching new products, and program quality can be maintained by adopting many of the total quality management processes common in manufacturing. Ultimately, however, learning networks do not manufacture products. The analogy, while useful, must not be taken too far. The goal of providing effective learning experiences must not be sacrificed in pursuit of greater efficiency. Striking the correct balance between the two is one of the primary responsibilities of the central management agency.

Research and Development

BEST COPY AVAILABLE

Typically a small "core team" focused mostly on learning-model evaluation and design leads the research and development (R&D) efforts. This team works closely with outside groups to identify and evaluate emerging trends and best practices that may be applicable to further enhancing the network. Research subjects include adoption of different teaching and assessment methods and their application to procedural, collaborative, and problem-based learning. This group is responsible for prototyping new technologies, such as simulations and virtual reality, case-based learning, and peer-to-peer collaboration. Using data provided by the operations-support and field-delivery teams, these prototypes can be rapidly evaluated, improved, and rolled out to the entire learning network.

Production

The production group is responsible for developing and implementing learning programs with direction from the R&D, operations support, and field delivery teams. Specific areas of focus include both designing and planning the instructional program. This includes the design and development of the curriculum, instructional material, and associated assessments. Once this is completed, translation and localization can be carried out—if required. Finally, the production group is responsible for quality assurance of the instructional material.

Operations Support

The largest of the central management agency groups, operations support is directly responsible for the delivery and support of all programs and services to the dispersed field delivery network. The operations support group provides hands-on support to the many field delivery organizations around all aspects of running their academy. Operations support is broken down into five main areas:

1. Program management: This function ensures the smooth transition and roll out of new programs and delivery systems to the field delivery network. This includes supporting recruitment of instructors and academies, as well as promoting and demoting academies.

2. Delivery support: This function directly supports instructors in the field. Through a central helpdesk or website and regular site visits, instructors are supported and taught about new features, techniques, and opportunities.

3. Field quality assurance: This function monitors academy performance and student results. It also investigates and resolves complaints.

4. Marketing and communications: This group provides academies with marketing materials to help attract students. It also supports academies of higher rank in recruiting other academies into the program.

5. Technical support: This group manages the network infrastructure and maintains levels of service.

Field Delivery

Field delivery is, by far, the largest part of any learning network. This function contains many varied sub-groups. Included here are the organizations or academies responsible for managing the delivery of instruction as well as the employees that work for these institutions, typically instructors and administrators. The students themselves are included in this group and provision is often made for alumni so that community and support can be provided beyond the immediate learning period. Field delivery is the last stage in the production line analogy. Equivalent to a manufacturer's distribution channel, field delivery involves the largest number of people and is the most difficult part of the learning network to change. As delivery organizations in the field mature, they often assume some of the operational and support roles (instructor training, delivery-system support and recruitment, etc.) for less mature organizations. This feeds the growth of the overall program.

Supporting Technology

Many effective large-scale learning networks have evolved without the extensive use of technology to support program delivery. However, the Internet has made possible lower-cost platforms to further enhance efficiencies in most areas: content authoring and management systems are available to support production of new programs; content distribution systems enable content to be delivered directly into the classroom; and assessment engines that enable the measurement of proficiency and learning management systems support the administration of academies and the tracking of student grades and certification. While all the components of a standard integrated learning management system are required for each academy, there is a need for network-level tools and services to administer the network of organizations and track instructors and students as they move between institutions. These tools are typically custom built, as few vendors of integrated learning management systems provide this functionality.

Applicability of Learning Networks

A learning network is most applicable when three key features are present. The absence of one of these features does not mean a learning network cannot work, but it does mean it may be less appropriate.

1. A blended-learning model is required because pure distance learning will not support the required access to people or equipment. In such cases, teamwork or social interaction may be an integral part of the instruction, or access to location-dependent specialist equipment may be mandatory.

2. A large number of organizations are able and willing to join the network and deliver the instructional program. These organizations can take many forms: a network of dealers, resellers, or agents; schools and adult education centers; or large organizations with many semi-autonomous sub-groups, such as government agencies, armed forces, and healthcare providers.

3. The target audience values certification and is willing to pay a reasonable fee and invest a significant amount of time to qualify. For example, certification may significantly improve employment or promotion prospects, or enable leisure activities.

Benefits of Learning Networks

Learning networks have many benefits. The network structure itself allows the costs of instruction to be spread across the entire network. The network often functions like a market; this prevents any one organization from making inordinate profits and also serves to keep costs at reasonable levels. The network structure also enables rapid reaction to market dynamics. New curriculum and assessment can be prototyped, refined, and rolled out to the entire network in very short time frames. These features support the rapid growth of learning networks.

The academy-based delivery model enables high-quality blended learning and—as a side effect—develops significant customer loyalty. Students and instructors meet at centers where they form communities that are surprisingly enduring.

Learning networks are massively scalable. They do not require a single, expensive, monolithic organization to deliver on a global scale. Indeed, global delivery is possible with just a few hundred people running the central management agency. By leveraging technology to streamline administration and delivery, the central management agency can stay in direct touch with many parts of the field organization.

Example Learning Networks

Many examples of learning networks exist, supporting different industries, professions, and areas of interest:

- Operation of Complex Equipment
  - National Association of Flight Instructors (NAFI)
  - Driving Instructors Association (DIA)
- Vocational Training
  - Cisco Networking Academy

    - Automotive collision repair (I-CAR)
- Education
    - Science Learning Network
- Leisure Activities
    - Scuba diving (SSI)
    - Professional Association of Dive Instructors (PADI)
    - British Sub-Aqua Club (BSAC)
    - Professional Ski Instructors of America (PSIA)

Cisco Networking Academy

The Cisco Networking Academy program is a comprehensive e-learning program that provides students with multiple levels and kinds of certified Internet technology skills. Initially focused on network system skills (Cisco Certified Network Associate and Professional CCNA and CCNP), the program has rapidly expanded both the geographical coverage and the program curriculum. The program now includes courses sponsored by IT industry leaders (including Unix and Web Design) and is offered by a wide range of high schools, technical schools, colleges, universities, community based organizations, and military academies worldwide. The fully web-based program provides educational content, online testing, student performance tracking, and instructor training and support. The instructor-led classroom structure leverages this technology while providing high-touch support for students.

Business Results

- 9,000 Academies
- 130 Countries
- Nine Languages
- 15000 Instructors
- 250,000 students
- 30,000 + examinations per day
- Support for three million page views per day
- 50-percent annual growth
- A global delivery network, including an advanced, scalable LCMS and LMS tailored for learning network support

The Professional Association of Dive Instructors (PADI)

PADI is the world's largest recreational diving membership organization. Membership includes dive businesses, resort facilities, academic institutions, instructor trainers, dive educators, divers, snorkelers, and other water sports enthusiasts. PADI is focused on maintaining industry standards for dive training, safety, and customer service by supplying a range of educational materials, training aids, promotional pieces, certification, and recognition materials to support the delivery and marketing of PADI programs.

PADI certifies multiple levels of instructors. Instructors, master instructors, and course directors all exist within the program, which employs strict educational standards to maintain worldwide consistency and quality. The program has a full-time quality assurance department and all student training is conducted by certified instructors.

Business Results

- 526,904 new diver certifications (worldwide, 2000)
- Since 1967, over 10,151,841 diver certifications issued
- 106,893 total PADI individual professional members (2000)
- 4,726 total international resort and retailer association members (2000)
- Active in over 100 countries worldwide
- Curriculum is delivered to training organizations via traditional methods books, videos, CDROM, etc.

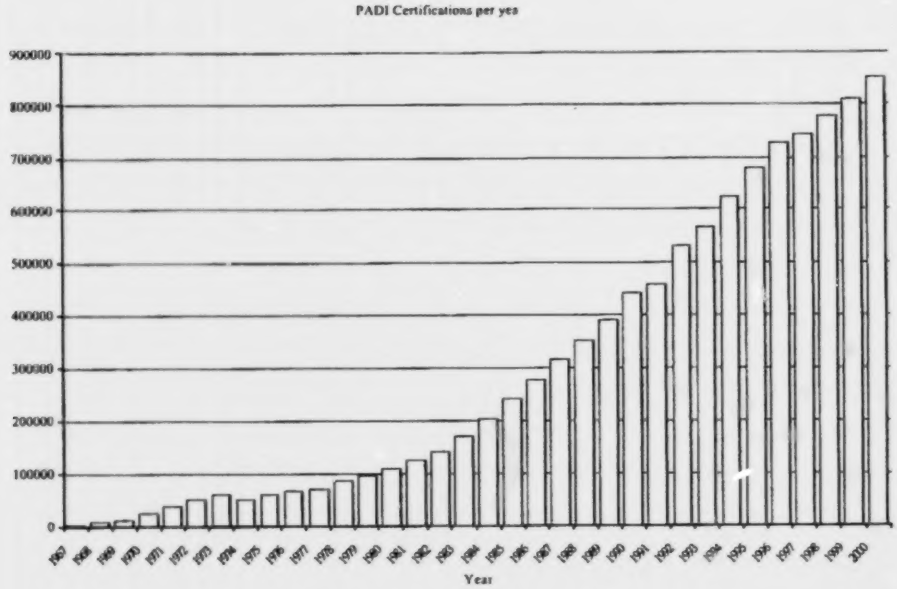

Figure 4: **PADI certifications per year since 1967**

Conclusion

Adoption and acceptance of e-learning is growing rapidly. However, there are classes of learning that are still best accomplished through the use of instructor-led training, leveraging physical classroom settings and resources. Learning networks offer a proven approach to building large-scale blended learning solutions. And emerging technologies can significantly increase the effectiveness of learning networks.

International E-Learning Business: Opportunities & Strategies

Dr. Joachim P. Hasebrook & Dr. Dirk W. Rudolph, efiport Inc.[1]

Abstract

Education is already a big business. E-learning, by making it easy to impart information and skills to anyone, anywhere, anytime, and for any purpose will grow the education market. As always, the big winners will be those vendors that identify and serve emerging and sometimes hidden markets. The biggest growth segments unleashed by e-learning are education for non-traditional students and the use of educational methods in related areas such as public relations, sales, and investor relations. E-learning permits dramatic expansion of the education market. While "distance learning" is the best-known example, we believe providing continuing education for busy professionals is a much bigger opportunity. E-learning is primarily about superior solutions for self-study and online courses. These solutions, however, can be readily adapted to sales and public/investor relations. In both cases, the object is to get information across to the recipient. While the education industry correctly emphasizes the learner, that does not mean there is no longer a need for teachers. Teaching and persuading have many things in common and can share many of the same advanced tools. Corporate training and personal career development are segments ripe for explosive growth. Businesses need to impart both general skills and company-specific information to their employees. They need solutions that are highly reliable, consistent, and available in order to bring new employees quickly up to speed. Increasingly, corporations are realizing that the Internet and extranets can be used to train customers and business partners, as well as persuade investors, consultants, industry analysts, and potential customers.

Key Enabling Technologies

The gradual development of e-learning standards will lead to interoperability between content, learning platforms, and testing. This, in turn, will make it easier and less costly to develop courses on highly specialized topics and for niche markets. To wit, the best tools will be available and affordable for use with all topics, whether popular or esoteric.

Networks will play a particularly important role, making it possible to deliver content and courses in new ways, and changing the way students, teachers, and others interact. The public Internet is central, but it is not the whole story. Private networks and virtual private networks (VPNs) will also play significant roles.

The Web is both a global marketing channel and a delivery vehicle. While the lack of significant local markets has been an obstacle to highly specialized courses, it is not the only obstacle. Just finding such courses can be a major problem. For the first time, there is a fast and convenient way to both identify and access specialized courses. The Internet can be used for real-time classes (distance learning) and non-real-time classes – or a combination of the two.

LANs enable classroom automation, and can be used to enhance the educational value of conferences and seminars. While schools have invested heavily in personal computers, they often put them in computer labs where students are taught how to operate them – but for no specific purposes. Wireless LANs enable distributing PCs throughout the school and moving them around as needed.

Virtual private networks enable education institutions to create virtual campuses with whatever geographic reach is desired. VPNs also enable enterprises to extend education to workers, business partners, and resellers in the field. The continued growth of VPNs, however, depends on the industry's ability to prevent major security breaches.

Mobile learning will make it possible for busy professional to pursue continuing education. Public wireless LANs and 3G wireless networks will enable users to remotely access courses, content, and other learning resources. Though some 3G wireless networks have been delayed, others haven't, and

BEST COPY AVAILABLE

the migration to 3G networks that support high-speed data is inevitable. (See our report: "Third Generation Wireless: Business Models & Strategies."

E-books have not had much success in the consumer market, but they could become a factor in the corporate training and post-secondary education markets. For example, the equivalent of several large textbooks could be stored in a much smaller and lighter weight package. E-books could also be used to train service technicians; after they complete the training the ebook becomes a convenient way of carrying a complete library of service manuals.

The development of multimedia content for education will create demand for better ways to search for and identify video and audio content. Thus, training and education in general may provide the stimulus for new products and services addressing this problem. The use of metadata and pattern recognition software are promising methods for cataloguing audio and video content.

E-learning products and services may also be enhanced through the use of speech recognition, text-to-speech, and natural language technologies. The use of voice technology is particularly useful in teaching and practicing foreign languages. Voice technology will extend the reach of online e-learning courses to any telephone. Thus, learners could study a few minutes here and there, in different places and at different times. For busy professionals, voice technology could prove helpful in squeezing learning into their schedules (for example, while commuting to and from work).

Copyright protection is a key concern for the e-learning industry. A number of solutions, generally referred to as digital rights management (DRM), do more than just protect content from unauthorized access and distribution. DRM can be used to control the number of times that material is viewed, whether it can be printed, how long it is accessible, and so forth. Thus, DRM will enable content producers to block sales of "used" content for which they are rarely compensated.

Key Business Opportunities

The biggest opportunities for e-learning are for content producers and distributors. E-learning enables those who have knowledge to reach a wider audience, both in terms of geographic reach and audience composition through the use of different versions (packages).

There are also opportunities for software developers. Learning/testing platforms, authors' tools, and virtual campuses are among the best. Online courses and mobile learning create opportunities for software that is highly interactive and can intelligently suspend/resume lessons as needed. There is still much to be done in development of custom courseware that adapts to the learner's needs, knowledge, and skill set.

Given the size and importance of the education market, one should not rule out the need for special hardware. For example, e-books should be adapted to the needs of students and trainees. Education, rather than the convenience of reading a backlit display in bed, may prove to be the bigger market for e-books.

There are numerous opportunities for e-learning portals, online universities, and mobile learning (m-learning) services. These service providers can also benefit from specialized tools. As telecom operators strive to move up the value chain, education and persuasion will prove key markets. We would not be surprised to see virtual network operators emerge, focusing exclusively on education and persuasion.

Main Driving Forces of Global E-learning Markets

Education is the second largest service sector in the global economy (health care is the largest), and K-12 is the largest segment within the education sector. It is estimated that worldwide education expenditures have reached US$2 trillion per year. E-learning accounts for perhaps 0.1% today; thus, increasing e-learning's share to a mere 1% would expand the market for e-learning products and services by nearly US$20 billion. According to UNESCO statistics, there were 1.15 billion students enrolled worldwide in primary, secondary, and higher education in 1997.

The key to e-learning firms' future profits is what analysts call "scalability." With traditional classroom teaching and training, class size is limited. For example, it is generally agreed that class sizes for continuing education seminars should not exceed about twenty students. This is also true for many higher education courses. The size limit, however, severely constrains profits. One hour of a teacher's time in class cannot generate more revenues than about twenty hours of seminar attendance. This puts a cap on the scalability and profit potential of traditional classroom education.

In computer-based training (CBT), the distribution of production costs between fixed and variable sources is radically different. The fixed costs of producing one hour of training are very high -- much higher than preparing an hour of traditional classroom teaching. But the variable cost of providing an additional hour of computer-based training is much lower. Thus, the average cost of providing an hour of computer-based training decreases with the number of students. The number of CBT students is not limited by classroom size and class manageability. Thus, the number of students worldwide for a specific CBT product determines the average cost per hour.

E-learning is also more scalable because the Internet makes it fairly easy to reach a worldwide market. The cost of marketing and distributing a course over the Internet is much lower than an advertising campaign using print media or sending CD-ROMs through the mail. It is the combination of worldwide market reach, low marketing/distribution costs, and a product with very low variable production costs that adds up to potentially high profits for e-learning products.

E-learning for K-12

The prospects for elearning in the K-12 market segment are very strong. According to UNESCO, there are currently 1,175 million students enrolled in K-12 institutions worldwide. Internet connectivity for secondary schools in most West European countries and the U.S. was estimated between 80% and 100% in the second half of 2000. The markets for primary and secondary education are the largest education market segments in the U.S. and worldwide. Expenditures in the U.S. for primary and secondary schooling reached US$371.9 billion in 1998, or 4.4% of GDP. Enrollment in the U.S. is expected to grow further. The study "The Knowledge Web" by Moe and Blodgett [2000] estimates the K-12 e-learning market in the U.S. at US$1.3 billion. They expect it to grow to US$6.9 billion by 2003.

E-learning for Higher Education

Higher education is a growth market. In the U.S. alone, 15 million students are enrolled in higher education. Worldwide, there are 84 million students pursuing higher education. Expenditures in the U.S. for post-secondary education, both private and public, are growing steadily, having reached US$146 billion and US$87 billion for the 1997-1998 school year in the public and private sector, respectively. The "Report of the Web-Based Education Commission to the President and the Congress of the United States" shows that growth in jobs requiring a higher education continues. According to the report, in 1950 the majority of jobs (60%) required no special skills. Today, 85% of jobs in the U.S. require an education beyond high school, up from 55% in 1991.

The Post-Secondary E-Learning Market

Moe and Blodgett (2000) estimate that the post-secondary online education market currently generates US$ 1.2 billion per year. They expect the market to grow to US$7 billion by 2003. Within this market segment, enrollment in distance learning demonstrates the growth potential of Internet-based course delivery. The graph below shows a sharp increase in enrollment in distance learning courses between 1995 and 1998. The "Agenda Project" report of the U.S. Department of Education (Office of Post-secondary Education) shows that the number of people enrolled in distance learning courses at post-secondary institutions in the U.S. nearly doubled between 1994-95 and 1997-98. The share of students enrolled in distance education as a percentage of total post-secondary enrollment was 5% in 1998, expected to rise to 15% by 2002. The "Report of the Web-Based Education Commission to the President and the Congress of the United States" shows that 710,000 students were enrolled in distance learning courses in 1998. The report predicts that enrollment will increase to 2.2 million by 2002. While 62% of four-year colleges offered distance learning courses in 1998, the share is expected to increase to 84% by 2002. In particular, online MBA programs are expected to grow rapidly. The global market for online post-secondary education was US$875 million in 1998 and is projected to reach US$3.9 billion by 2002. Crucial to the development of e-learning courses is the availability of technology-based content. In 1998, there was already a large selection of academic learning software

(3,300 titles) available. Most of this content is CD-ROM-based; the potential for using such content to supplement online courses is significant.

E-learning for Continuing Education

Many non-profit universities, such as Pennsylvania State University, the University of California at Los Angeles (UCLA), and the University of Wisconsin, have a long tradition of developing continuing education programs and courses through their extensions and outreach divisions. Many of these programs have begun to use online course delivery. For example, the School of Continuing Education at New York University, one of the largest programs in the U.S. (60,000 students), offered 30 online courses in fall 1997. Penn State World Campus wants to develop 30 certificate programs based on more than 300 courses. The University of California-Berkeley Extension also offers a large number of certificate courses online. Another e-learning pioneer is Athabasca University (Alberta, Canada) (http://www.athabascau.ca/) Its Centre for Innovative Management was the first to offer a complete MBA program online (in 1994). Many traditional c-learning firms are in the process of entering the e-learning market. Examples are Achieve Global, ARIS Coporation, Development Dimensions International, DeVry, ExecuTrain, Franklin Covey, Global Knowledge Network, Learning Tree International, New Horizons Worldwide, and Provant. For continuing finance education, New York Institute of Finance (http://www.nyif.com), Canadian Securities Institute (https://www.csi.ca/pub/en/index.html), and the efiport AG in Germany (http://www.efiport.de) now offer web-based courses.

E-learning for Corporate Training

E-learning for the corporate market is a function of B2B e-commerce. The second largest e-learning segment is also the quickest at adopting new technologies: the corporate training market. For example, a single U.S. company such as General Electric spends US$500 million on training and education per year.

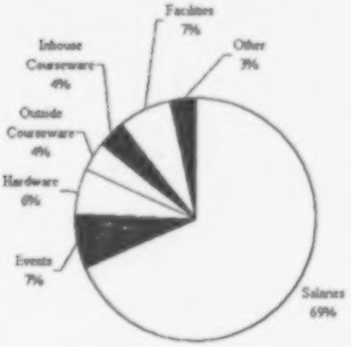

Figure: Annual global training expenses [2]

Corporate universities are a particularly interesting e-learning segment. In the U.S., the number of corporate universities has grown from 400 to 1,800 over the last thirteen years. According to the "Report of the Web-Based Education Commission to the President and the Congress of the United States," 40% of Fortune 500 companies have established a corporate university. A survey conducted by Corporate University Xchange suggests e-learning will rapidly gain market share in corporate training. In 1999, traditional classroom training (c-learning) was the dominant course delivery mode with an 80% share. By 2003, Corporate University Xchange predicts this share will decline to 60%, with e-learning grabbing the remaining 40% share.

Training Magazine estimates roughly US$62.5 billion was spent on formal training by U.S. organizations in 1999. This is an increase of 24% compared to 1993. The major share (44%) was spent on trainer salaries, another 24% went to outside providers of training products and services, and the rest was used for facilities, materials, hardware, seminars, and conferences. This means outsourced training providers captured a 24% share of the corporate training market, which corresponds to US$15-17 billion.

---

[2] From: http://www.internettime.com/itimegroup/market.htm

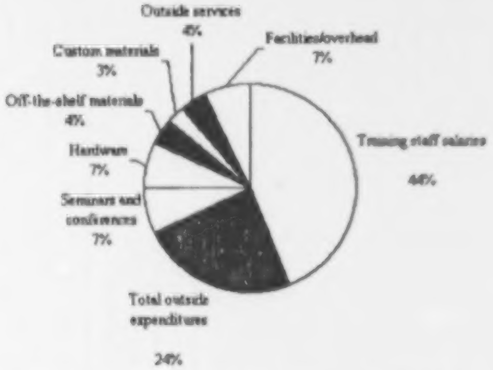

Figure: Corporate training budgets, U.S. (1999)[3]

Outsourced training accounts for nearly 30% of information technology (IT) training but less than 18% of soft skill training (e.g., seminars on time management). Around 10% of the IT training is technology or Web-based, whereas only 3% of the soft skills training is mediated through technology or the Web. The e-learning segment of the corporate training market in the U.S. accounted for about US$550 million and US$ 1 billion in 1998 and 1999, respectively. A particularly interesting segment is corporate IT training. In 1999, more than 2.2 million IT specialists worked in core IT occupations (computer scientists and engineers, systems analysts and computer programmers). Training Magazine notes that one third "of all employer-sponsored training in the U.S. is devoted to teaching people about computers." Today, technology-based IT training is a relatively small market in the U.S. with US$2.3 billion in revenues. However, this will change soon.

E-learning for Non-traditional Market Segments

There is a clear trend towards higher education for non-traditional student groups in the U.S. Between 1970 and 1993 the number of traditional students (age 18-24) enrolled in higher education increased by 35%. During the same period, the number of older students (above age 40) increased by 235%. Surprisingly, traditional undergraduate students (age 18-22 and who live on campus) made up just 16 percent of post-secondary enrollment in 1999, according to an article in Newsweek (April 16, 2000). Thus, traditional undergraduate and graduate students now account for less than one-third of U.S. higher education enrollment. Part-time and older students account for two-thirds of those enrolled in higher education. These non-traditional students are prime targets for e-learning because they are highly motivated but can't spend all day in classrooms. The primary target group for private education is self-directed, self-motivated, and ambitious students with job experience and clear learning objectives. A pioneer in for-profit adult education is the University of Phoenix. They have shown that providing higher education for non-traditional student groups is financially viable.

Customer Training and Client Education

E-commerce has clear competitive advantages for information-intensive products and services. The ability to employ e-learning for customer training is one of them. One example are the online computer courses known as "Educate U" (www.educateu.com), developed by Dell Computer Corporation and the Web-based training firm SmartForce. Anyone can take two basic courses for free.

---

[3] From: Ruttenbur, Spickler, and Lurie, [2000]. Source: Morgan Keegan estimates, National Center for Education Statistics, Training Magazine

Dell customers may receive three more courses for free, after which they become eligible to purchase courses from a selection of about 1,000 courses priced between US$5 and US$200 each.

Major Conclusions

- E-learning does not replace traditional classroom education. Instead, it expands the market for education products and services. Thus, e-learning assists the growing population of non-traditional learners, many of whom must divide their time between work and school, to pursue an education.
- E-learning solutions can be applied to non-education markets such as public relations, sales, and investor relations. The same tools developed to facilitate imparting knowledge to students can be used with great effect in persuading customers, investors, and commentators.
- Corporate training, career development, and expert enhancement are areas ripe for explosive growth. E-learning facilitates cost-effective production and delivery of courses for specific companies, jobs, and skills. It also enables organizations to adopt standard courses that can be kept up-to-date without confronting a logistical nightmare.
- E-learning technology enables course authors and producers to readily re-use content in different courses or different versions of the same courses. Thus, e-learning courses can be more customized than traditional c-learning courses. The ability to address special needs with minimal effort ensures the broadest possible market for any given content.
- While there has been much interest in using the Internet for "distance learning," its use as a global distribution channel presents a much bigger opportunity. Highly specialized courses for which there is insufficient local demand may do well in the global market. The Internet can also multiply the success of courses that do well locally.

Table. Growth prospects for e-learning technology in various market segments and time frames.

- Virtual private networks enable creation of virtual campuses that extend out into the local community and beyond. In addition to distributing course content, VPNs can be used to facilitate communications between learners and instructors, for collaboration between learners, and to administer tests.
- Wireless LANs will enable K-12 schools and universities to provide a range of advanced services for students, faculty, and administrators. In K-12 schools, wireless LANs facilitate the use of PCs and the Internet in classrooms and laboratories that lack network wiring. Wireless LANs on university campuses will permit students to access a variety of resources (such as online libraries) from their own laptop PCs and PDAs.
- Third generation wireless technology will enable mobile learning (m-learning). This will open entirely new opportunities for busy professionals who don't have time to attend classes. It will also spawn development of courses designed for "bursty" learning.
- Digital rights management (DRM) can be used both to protect content and facilitate creation of different versions. DRM technology was primarily developed to prevent unauthorized access and redistribution, but it can also limit authorized use to create targeted versions at different prices for specific customer groups. Thus, a quick refresher course that expires in two weeks could be offered at a low price.
- E-books have not experienced much success in the mass market. However, they are a perfect fit for many e-learning markets. E-books simplify distribution of the latest versions of service manuals and catalogues. They also enable non-traditional students and field workers to carry a library of reference materials in a small and lightweight package.

Supporting decentralized education with personal technologies

Ulf Hedestig, Victor Kaptelinin, Carl Johan Orre

Abstract: The paper deals with the use of personal technologies in decentralized university education. Decentralized education, delivered to off campus students located in the same geographical area, is a hybrid genre combining features of both on campus and distance education. The paper reports two studies. The first study focussed on communication patterns among students in a regular decentralized education setting. It was shown that (a) there are obstacles preventing the students from developing communities of practice, and (b) some of the obstacles are likely to be eliminated to alleviated with personal technologies helping the students to get an access to various resources and to communicate to each other. The second study included providing a student group with a set of PDAs and analyzing the impact of the technology on students' learning and communication patterns. The prospects for using personal technologies in decentralized education are discussed.

Introduction

Online courses and educational programs provided by universities for off-campus students have become increasingly popular during the last decade. One of the main factors contributing to the widespread interest in online courses is the freedom that the students are assumed to have when choosing time and place for their learning activities. The transformation of traditional learning into the so-called "e-learning" follows other general societal trends induced by information and communication technologies (ICT), such the trends towards e-commerce, e-democracy, and e-government. For universities the idea of a virtual campus has been put forward as a possible solution to the problem of overcrowded classrooms that impose constraints on on-campus teaching and learning. New demands for virtual campuses have also been articulated by regions and municipalities, which want to set local university programs to meet the needs of their local labor markets.

The changes in university education are associated with new challenges for teachers. Many teachers have to combine traditional on-campus teaching with giving distance courses or hybrid types of courses, such as decentralized ones. The trend toward extending university education beyond campuses also has an impact from students' perspective. On-campus education takes place in a setting that evolved from centuries of experience with supporting traditional classroom teaching. The setting provides a coherent context that is rich in various types of resources crucial for successful teaching and learning. These resources include a possibility for students to participate in a variety of regular classes, communicate with fellow students, have an access to university library, and various types of advanced technological resources (currently they often include a high-speed connection to the Internet). Besides, on-campus settings are characterized by physical presence of teachers, counselors, student unions, and so on. This context supports an enculturation process, so that the students can develop different communities of interests. On the other hand, in case of decentralized education and distance education, there is a limited access to resources, such as library facilities, teachers, computer capabilities, connection to the Internet, etc. Besides, there is often no predominant context for teaching and learning, as it is in the case of on-campus education. Students participating in decentralized university education have to study in a number of contexts, not only in formal educational settings, such as a local study center, but also at home, at workplace, on a bus, etc. Since students' learning activities are distributed over both time and space, it is more problematic to establish communities of interests. As a result, for many distance/decentralized education students learning is a more lonely process than it is for on-campus students.

Universities have been provided with information and communication technologies supporting the structural changes towards "more virtual" educational settings. Many discussions related to the educational use of technology have been focussing on finding standard ways of successfully using hardware and software depending on a certain course content. However, when education becomes more diverse other demands also come into the foreground. Given that the learner-centered teaching and learning perspective is crucial for education, and that there are profound individual differences between students in mental processes underlying learning and cognition (Gardner, 2000), it is necessary to take into consideration the specific contexts and circumstances, in which students live and study. According to Reigeluth (1999) in development of educational settings and pedagogical methods it is important to focus on customization instead of standardization. If customization is to be taken seriously, one has to recognize that proliferation of diverse educational forms forces students and teachers to become more mobile, in the sense that the context where those actors act changes all the time. Further, teachers have to be aware that students who attend their courses have different motives and prerequisites. Implementation of educational technologies in education has to deal with the above issues and complicated contexts. Finally, one more consequence of the customization perspective is that the traditional top-down approach to creating learning environments, that is, an approach, according to which webmasters and technicians construct an ICT-based environment, should be replaced with an alternative "bottom-up" approach, when teachers and students are more actively involved in the design process.

> *"The best way to support learning is from the demand side rather than the supply side. That is, rather than deciding ahead of time what a learner needs to know and making this explicitly available to the exclusion of everything else, designers and instructors need to make available as much as possible of the whole rich web of practice- explicit and implicit, allowing the learner to call upon aspects of practice, latent in the periphery, as they are needed"* (Brown and Duguid, 1993, p 13)

The starting point for both this paper in general and the project reported below has therefore been an attempt to investigate from a students' perspective the technologies they actually use and how communication and behavior patterns evolve with the use of different media. One of our previous studies (Hedestig and Orre, 2002) showed that students communicate through other channels than can be traditionally found in ICT-based learning environments. In particular, the use of mobile phones has become very common in the last several years. The majority of the students participating in the study reported in this paper (that is, 31 out of 32 students) had mobile phones. A promising type of tool to support students in learning settings typical of decentralized education could therefore be mobile artifacts, since certain types of such artifacts have been already adopted by students and they are flexible enough to deal with the complex nature of the reality of distance and decentralized education, mentioned above.

A case for personal technologies

In recent years mobile artifacts, such as mobile phones and handheld computers (PDAs), changed our ways of interacting with colleagues and friends. There is an appealing "aura" around these devices attracting people interest and stimulating the willingness to use them. With a tremendous speed and smoothness mobile technologies have been assimilated in our working life, as well as our everyday life. However, what are the attributes and the features of mobile technologies? Before we answer this question it is necessary to define what we mean by mobile artifacts. We would like to address the notion of personal technologies as it was introduced by Sharples (2000) and relate it to our discussion of mobile artifacts. According to Sharples (2000), mobile technology can be considered as a subset of personal technologies. Personal technologies in a broad sense include several other technologies. The main feature of various personal technologies is that we use them for organizing our everyday life. Digital date books or PDAs contact lists on IRC clients and mobile phones provide some examples of personal technologies. In this paper we will discuss characteristics of mobile technologies, which, from our point of view, can have an impact on the design of learning environments.

Characteristics of mobile technologies

Contextual features of mobile technologies are related to processes and factors at the micro-social level, that is, interactions among and between people (Townsend, 2001). Interpersonal interactions are the domain

BEST COPY AVAILABLE

where we find the most challenging and intriguing characteristics of mobile technologies. For instance, Kopomaa (2000) describes the mobile phone user as a newly emerged flaneur reclaiming public places and sites. Due to the ability to get mediated access through mobile technologies people are free to choose where and when to interact with others, and place is no longer a restriction. Rather, choosing or finding a place became a routine issue that parties involved in a conversation via a mobile phone have to deal with, often being influenced by rules and habits inherited from fixed-line communication. Interpersonal interactions are dynamic and undergo developmental changes, so that people face a special problem of maintaining relations with other people through different means. In the past fixed-line telephones, postcards and letters were used, in addition to face-to-face meetings, to maintain relationships. Today, even though we still use fixed-line phones, it is mobile phones, e-mail, and different types of instant messaging systems that are more often chosen as a communication channel. Postcards and letters are still playing some role but their use decreases due to decreasing costs and efforts related to the use of alternative media.

Maintenance of personal relations is one aspect of personal technologies, relevant to their use in education. Another aspect related to contextual features that needs to be taken into consideration is the possibility of micro-coordination. With mobile technologies we can co-ordinate our activities with others more easily. This is a type of the use of technology that can be found among young people as well as among families. If one drives home from school and stops by a grocery store, a brief phone call from one's mobile phone can help to decide what to buy and bring home.

Flexibility is a feature that can be discussed and analyzed from different perspectives. Mobile artifacts, such as handhelds or mobile phones, have both a personal dimension and a public dimension, supporting activities taking place during either leisure or working time. Greenberg, Boyle and Laberge (1999) refer to personal artifacts as those that are owned by one person and public artifacts as those that are created and collectively owned by co-operating group members. The above distinction can be exemplified by a student group working with an assignment, where each student can use his or her handheld to access two types of repositories: (a) personal repositories, e.g., contact lists, personal files and notes, and (b) public repositories, e.g., course schedule, class discussions, and other resources from the common information spaces. It is important to take into account that there is a tension between these domains. What is socially acceptable in one setting is not necessary acceptable in another one. Sharples (1999) describes mobile technology as potentially disruptive when use patterns collide with established norms and values. The example he gives is a mobile phone ringing in a classroom. The signal is irritating both for the owner himself, who feels guilty for forgetting to turn off the device, and for the teacher and fellow students, who experience an interruption of the lesson.

Mobile technologies play different *roles* in different situations. The user and the needs that currently are the most important ones determine a specific role to be taken. For instance, Ling (2001) illustrates different motives behind adopting mobile phones through the following example. Imagine that someone, person X, travels from point A to point B. For X a mobile phone can be a safety device giving a feeling of security while traveling if something happens. For people who are waiting for X at point B a mobile phone can be used, if needed, to notify X that they are going to be late. Besides, people at point B can be confident that if something happens to X, he or she will notify them, as well. Ling & Haddon (2001) discuss motives such as accessibility, display, coordination and security/safety indicating that these motives have generational bounds and social needs that is determined by contextual perquisites. These and other examples clarifies the role and the mediated effect of mobile technology to extend beyond the tool view.

Thus, personal technologies, such as mobile phones, may play numerous important roles in our society. Studies show that these technologies answer to the needs and hopes of the modern individual and incorporation of these technologies into our way of life is a two-way process. Not only is the device being adapted to our everyday practices; our practices also change as a consequence of the use of technologies (Hedestig, Orre, 2002).

Mobile technologies in learning settings

Teachers become mobile due the fact that higher education undergoes similar structural changes as industry does, when considering the effects of the development towards the information society. Virtual universities often create new demands for teachers' mobility by introducing new forms of education. Decentralized education and distant education, for instance, force teachers to travel to give lectures and provide assistance to students. Maintenance of resources connected to a course, as well as maintenance of relations with fellow teachers can only be done by means of different technologies that overcome constraints associated with time and place. At the same time, it is necessary for the teacher to perform micro-coordination with the family as well. Existing technologies in learning environments lack the flexibility necessary to deal with all these circumstances, and therefore teachers have to adopt other technologies in order to attain these goals. One candidate technology for supporting teachers in mobile work settings, which we mentioned and discussed above, is a mobile technology integrating public and private environments.

Students are as well affected by these changes, since education becomes more virtual and accessible "anytime, anywhere". Students engaged in decentralized and distance education are more differentiated in age, background, etc, comparing to students participating in on-campus courses and programs. This means that teaching and learning, as mentioned above can occur in different places (e.g., at home, on campus, or at work places). In these environments different means of communication and collaboration are necessary. Existing technologies can lack appropriate features to support informal and formal communication. The learning process contains highly situated and collaborative elements, and the place of learning can be defined as the place where connections to social networks exist and are accessible (Hedestig, Orre, 2002).

Since late 90s there has been an increased use of mobile phones among all age groups (Ling, Vaage, 2000). New communication patterns have emerged with the advent of these devices and new cultures of use have been built around these technologies. The phenomenal success of adopting these devices in everyday life of millions of people can be used as a promising and potentially instructive example in designing architectures of new learning environments. Recently there has been a growing interest in the use of personal technologies in education, especially within K-12 settings, where these technologies open up new possibilities for children to get a better access to different resources (Danesh et al 2001). The traditional way to use computers in education has been to make computers centrally located, e.g., in computer labs. Such an arrangement has resulted in a limited access to technology for students. Since placing computers in one specialized location isolates them from other educational settings, the technology has been almost exclusively used for computer-oriented activities and not for domain-oriented or subject-oriented activities (Inkpen, 1999). Recently a number of pilot projects tried to find out how personal technologies can be integrated into a wide variety of learning settings. These projects have focused on specific issues, for instance, tests and assignments (Chen, Myers and Yaron, 2002), collaborative learning (Landay 1999, Roschelle and Pea 2002, Luchini et al 2002), and distributed training of medical students (Lundby, 2002).

Mobile technology and competence development in work settings has also been a popular topic of research since the late 90's. The work conditions in the "information society" have been recognized as demanding more distribution and mobility of the work force (Kristoffersen and Ljungberg 2000) In IT-based work settings mobile workers need new types of competence development opportunities, which are not restricted by time and space. Several recent research initiatives have been initiated to face this challenge by focusing on new models of using mobile technology in competence development (Hardless et. al. 2000) and supporting knowledge management (Fagrell, Forsberg and Sanneblad 2000).

A mobile learning project

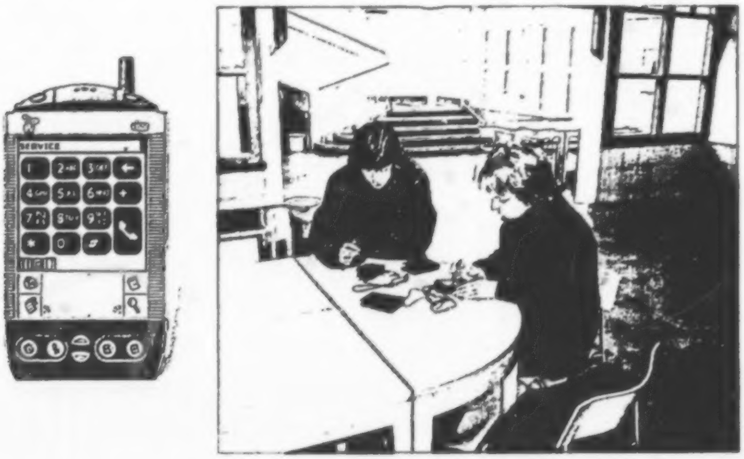
A project reported in this paper was initiated at the Department of Informatics, Umeå University, during Fall 2001 (Orre, Hedestig, Kaptelinin, 2001; Hedestig, Kaptelinin, 2001). The aim of the project was to understand existing communication patterns and use of mobile artifacts among undergraduate students and how this knowledge can be used to inform design of learning environments for distance and decentralized education. The project had adopted a bottom-up approach to designing learning environments, that is, attempted to view teaching and learning from students' perspective. In other words, the goal was to understand how students learn and interact with each other. A class of 32 students in a town located 150 km from the University campus attending a decentralized undergraduate program in Informatics took part in the project.

Framing Communication Among the Students

The first phase of the project was to deal with how the students socialized and communicated within a group of classmates. The aim was to reveal student's communications patterns and then capitalize upon this knowledge when introducing PDAs and further investigating the impact of technology on students' learning activities. Every student participating in the project was asked to keep a diary of his or her communications. The students recorded to whom and when and by what media they communicated. The diary data allowed us to reveal several patters of communication showing how different groups within the class emerged and evolved.

Another source of empirical data were interviews used to cross check the data from the dairies and to capture aspects that were hard to find in the dairies. Interviews were both conducted with students either in small groups or individually. We found group interviews a useful technique both as a source of new data and as a cross-reference to the dairies and the individual interviews. The interviews were recorded and then transcribed.

The second phase of the project was to focus on the adoption process. Twenty PDAs were distributed among the students approximately three months after the initiation of the first phase. We video-recorded the distribution of the PDAs the students in order to get hold of their initial response in the first encounter with the devices. We followed up the introduction with individual interviews conducted, respectively, one week and two weeks after the distribution. All PDAs were equipped with a mobile phone Springboard module, which enabled the students to use PDAs as a mobile phone and connect their PDA to the Internet. One reason for combining PDAs and the mobile phone module was our belief that the hybrid bridging two worlds - the world of the PDA and the one of mobile phone - is one of the most promising directions of the development of mobile technology. The objective of the study was an investigation of the feasibility of the artifacts for problem solving and the attitudes of the students, including their feelings and concerns experienced during the use of the devices in their studies. An important goal of the project was an attempt to integrate the above devices in the student's everyday life and make these devices a natural part of the ecology of learning environments, and thereby follow the developmental process of the mobile technology in use.



a) b)

Figure. 1. (a) The personal technology employed in the study and (b) a typical use situation.

Supporting Horizontal Communication

Due to a lack of resources available at a local study center, the students have formed study groups that regularly met and provided an important support for individual learning. In these groups a work practice had developed, where some students would take the role of a teacher and help the others to deal with the problems and difficulties they encounter. The traditional models of communication between the teacher and students, which are typically based on the idea of vertical communication, did not apply to the above interactions in study groups. Participating in the study groups was shown to influence students' attitudes towards technologies used in education. For instance, sending e-mails to the teacher was perceived by the students as a rather formal means of communication. It was also considered too slow in terms of receiving prompt replies to students' questions. It took a few days for the teacher to deliver an answer, and by then, the question was usually already discussed and dealt with in a study group. Therefore, the answer given from the teacher was more of a confirmation of the solution already developed within a study group. The emergence of study groups indicates the need for supporting horizontal communication in order to maintain and coordinate educational activities, both formal and informal. It can be concluded that the flexibility of means supporting horizontal interaction is an important

BEST COPY AVAILABLE

resource helping students to deal with the variety of contexts in which they learn. It was found that the observed increase of frequency of communication over the course of the study could be attributed to an increase in communication through horizontal communication channels (Hedestig, Orre, 2002). The students used these channels when studying at home or being located at some other place than the study center. In either case the mobile technology described above supported the students in being connected to networks of peers and being a part of a community of learners.

Our findings indicatess that in decentralized learning settings there are patterns of the use of *information* and communication technology, which are not adequately supported by existing technologies. Despite having an access to a variety of information and communication technologies, such as email and course websites, which are common artifacts in distance education, students preferred other, more mobile technologies in their interaction with each other. It can be concluded that decentralized education setting, heavily relying on more synchronous interactions, requires the participants to be more mobile

The Students Adoption of Mobile Technology

After distributing the set of PDAs we have carefully followed the process of adoption of this technology by the students. Our data indicates that the strategy of adopting the technology, employed by the students, was successful and the students have incorporated the PDA in their everyday life in a number of ways. We found that high motivation of the students, based on their interest in technical artifacts, positively affected the process. The students began to practically use the artifacts in an early state of the adoption process. The use of the calendar provided by the PDA replaced the use of ordinary calendars. Even those students, who never used a calendar for scheduling and planning their activities before, started to use the PDA as a digital calendar. It was also found that earlier experience of the students with mobile phones was one of the factors affecting their initial rejection of the mobile phone module. Due to low speed of transmission and low quality of the speakers of the module, which were inferior to the ones typical of conventional mobile phones, the majority of the students rejected the module in the beginning. Later on (in spring 2002) many of the students who rejected the phone module started to use it since they found new possibilities of using it in their everyday life. The PDA itself has been a success with the students. Our interviews indicate that the students especially appreciated the color screen, processing speed, and other advanced technical features. An interesting finding was that the hybrid device provided to the students was not considered as a single unit. The students always referred to a PDA and a mobile phone module as two different devices.

We identified two types of patterns in the students' process of technology adoption. All students had an intensive exploration phase in the beginning of the process. After that about 2/3 of the students started to use the PDA practically in their everyday life, while the rest (approximately 1/3 of the students) continued their exploration (Jacobsson och Jonsson, 2002). Even though initially the applications run on the PDA were only single-user applications, the process of technology adoption cannot be considered a purely individual process. It can be seen as a socially distributed activity. The students actively shared their experiences with each other, for instance, by exchanging software, encouraging each other to try new features of the technology, and providing help.

Conclusions

The studies reported in this paper call for three main conclusions. First, they show that there is an apparent need for personal technologies in education. Analysis of existing communication patterns among undergraduate students taking part in decentralized education had revealed a number of needs that cannot be addressed by current technologies. Decentralized education to a large degree consists of what can be called "mobile learning". Accordingly, the students need to get an access to course materials, to the teacher, and to fellow students when being located in a wide range of physical and social contexts. Currently the students have to rely mostly on conventional mobile phones, which have substantial limitations as a mobile learning technology. Therefore, first conclusion from our studies is that there is certainly a niche for new types of personal technologies, such as PDAs, in decentralized education settings.

The second conclusion based on preliminary results of our pedagogical intervention, in which a set of PDAs was provided to a group of students, deals with the adoption of technology. Our data shows that assimilation of personal technologies into everyday practices of students does not happen immediately. The group is appropriating the technology over the course of developmental changes underwent by their learning activity as a whole.

Third and finally, our data indicate that the most important problems with personal technologies are related not to the technologies themselves but to the type of coordination between personal and public artifacts and between individual and collective learning activities that can be supported with personal technologies (cf. Kaptelinin, Cole, 2002). The criteria of what is a useful and usable personal technology depend on the social context of decentralized learning. For instance, the possibility to send email messages or use an instant messaging system, provided by PDAs, is important not only because it allows a student to get in touch with a teacher or other students. Mobile phones can also be used for communication between participants in a decentralized course. However, as opposed to mobile phones, PDAs allow for establishing communication without violating rules and norms existing in the social context. A student can potentially get a prompt reply from a teacher without the distraction associated with the use of a phone. Therefore, designing successful personal technologies for decentralized education requires that, on the one hand, an understanding of the social context of this type of educational setting and, on the other hand, a coordinated development of technological support for both individual and collective learning activities.

A Media Rich Interface vs. a Simple Interface for Interactive Television

Anders Hedman , Sören Lenman

Abstract We compare and discuss the results from two user studies of interactive television (ITV) with a total of 50 subjects. The interfaces of two different ITV information services were studied: one with a place-like interface rich in graphics, animation and audio, and the other a simple interface with text and still images. In the first study, which evaluated the place-like interface, problems occurred with the mappings of the DTV-remote buttons and with the basic multimedia-interaction techniques used in interface. In the second study it was found that factors of concrete and conceptual nearness, with respect to the TV show, should be taken into account when evaluating the ITV service.

Introduction

ITV (Furth et al 1995, Ju et al 1994, Koller et al 1997, Srivastava 2002) allows for the development of graphically rich services with novel interfaces. ITV services surpass the limits of traditional text-TV based services in that they can resemble PC based multimedia applications. The resemblance is not perfect however, for ITV services multimedia is generally of lesser quality than traditional PC-based multimedia. The television screen, with low resolution and slow refresh rates, is not ideally suited for complex interfaces and the hardware performance of an ITV set-top box is drastically inferior to that of a standard PC. The current state of the art of ITV put developers in a dilemma. While they may recognize the possible gain of designing new and novel interfaces for ITV services, they also see the practical problems involved in such endeavors. On the one hand, if they develop simple interfaces modeled largely on traditional web sites (with e.g., navigation frame on left, content frame on right) they can be fairly confident that the design will at least work in practice. On the other hand, web-style interfaces may not be the best or even especially suitable for ITV services.

In what follows, we examine the results from two case studies of interfaces for interactive television. We discuss results on navigation, organization and level of engagement. The first case study was undertaken to help Teracom, a Swedish broadcasting network operator, evaluate a prototype ITV service with a place-like interface for educational TV. The second case study was conducted to guide The Swedish Educational Broadcasting Company (UR), a public service broadcasting institution, in designing simple user interfaces with text and still images for ITV information services in distance-learning.

Definitions

ITV can be implemented and deployed in various ways. In this paper interactive television (ITV) is seen as consisting of three parts:

(1) the ITV equipment which includes a remote control and a set-top box
(2) a digital TV show
(3) an interactive information service, complementing the digital TV show

The TV show is digital, but not interactive per se. Any interactivity is added by an ITV service, i.e., an interactive information service for digital television (se figure 1 for a screen shot of a service that was examined in one of the studies in this paper).

Figure 1: A sample screen from an ITV information service for a TV show about houseboating

First Case Study Set-up

Equipment

A prototype ITV application developed with Macromedia Director™, running on a standard PC, and displayed on a TV through a Nokia™ set-top box was used in the study. The trials took place in a furnished living room (with e.g., a couch, framed paintings, and green plants). User explorations and conversations were video taped. The camera captured users and what they saw on the TV (trough a split signal cable to a second TV). The place-like environment was a simulation with a series of photographs. The ITV package permitted users to "drive" down a road using a remote control and reach interactive stations (movie clips, texts, and still images). The TV show was an educational TV show about the history of Sweden.

Subjects

20 subjects, age range 25-60, 12 female, and 8 male took part in the study.

Procedure

Each person participated with a friend, i.e., they formed a pair with someone they knew and felt comfortable with. Each pair was asked to imagine themselves as being part of a study group on digital media. The scenario was that a group met weekly to discuss digital media applications. Next week they were to discuss the application presented to them in the trial. The subjects were given minimal operating instructions and asked to explore the service so that they could report on it at the study group meeting. The experimenters then left the room to allow the subjects to explore the simulated ITV service on their own and discuss their experiences more freely. All trials were video taped and at the end of each trial, the subjects completed a questionnaire. Lastly, the subjects were interviewed. Trials lasted for about 45 minutes (including a 15 minute interview). The scenario was purposefully open-ended because one important aim was to approximate the natural viewing situation of someone getting started with the ITV service at home. Moreover, this open-ended scenario also allowed for testing the whole of the ITV service. Since no previous studies had been performed on the service it was important to conduct an explorative study. The scenario did, however, provide the subjects with a sufficiently concrete task so that they did not feel lost.

BEST COPY AVAILABLE

Second Case Study Set-up

Equipment

A Sagem™ development set-top box with a remote control was used. It is similar to an ordinary Sagem™ set-top box, but has added functionality. The development set-top box and an ITV SDK (Software Development Kit) allow developers, to develop ITV services, and test them together with simulated TV shows. A video mixer was used to capture the TV screen (the simulated TV show and use of the ITV service). Thus both user reactions and what they saw on the TV in front of them was captured side-by-side on a single tape. The TV show was an educational TV show about house boats, and the ITV service complemented the TV show by providing images and texts about house boats.

Subjects

30 subjects participated in the final study: 20 were male, and 10 were female. The age range was 20-50 years.

Procedure

The procedure was the same as in the first study.

Results from the Case Studies

It is challenging to try to give an accurate comparison of two interfaces used in different applications, and tested in different studies. Not least, because the user groups might be incomparable. We have focused on three dimensions that we find concrete and possible to compare, although the last dimension (level of engagement) might, admittedly be highly influenced by the first two (ease of navigation and perceived organization). The questionnaires from the two studies revealed that the two ITV services from study one and study two received markedly different ratings on ease of navigation, organization, and on how engaging they were.

	Disagree completely	Disagree partly	Agree partly	Agree completely
Study 1: Place-like, media-rich interface				
Easy to navigate	30%	10%	30%	30%
Clear organization	50%	20%	25%	5%
Engaging	45%	35%	10%	10%
Study 2: Simple interface, text and still images				
Easy to navigate	7%	17%	3%	73%
Clear organization	17%	13%	13%	57%
Engaging	70%	10%	20%	0%

Table 1: Questionnaire responses for the two ITV-services from study one and study two with respect to navigation, organization and level of engagement.

On the one hand, the ITV service with the place-like interface was perceived as engaging but somewhat cumbersome to navigate and understand. On the other hand, the ITV service with the simple interface was easy to navigate and understand, while not being particularly engaging. This is just what might be expected, the novel, graphically rich interface is engaging but non-standard and consequently cumbersome to use. The simple interface, in contrast, is standard, but rudimentary and not very exciting. However, our analysis in the discussion section also gives another story.

Discussion

Navigation and organization issues of the service with the place-like interface

The video tapes from the study with the service with the place-like interface were transcribed and coded. It turned out that majority of the sentences involved problems in using the interface. That the service was still perceived as engaging could be seen as indicating a potentially high value in using non-standard media-rich interfaces for ITV services. However, the content, among other factors, could have influenced the ratings on perceived level of engagement.

Closer examination of video sequences of breakdowns indicated a major problem with the ITV service with the place-like interface. Many subjects were frequently "stuck" and found themselves staring at the remote control. While users could go forward and back with the top and bottom buttons, it was impossible to go left and right with the left and right buttons. These latter buttons were used for content selection. Thus the buttons were mapped according to a cognitively dissonant schema. Cognitive dissonance (Festinger 1957) occurs when one must choose between incompatible beliefs or actions. Great dissonance is created when alternatives are equally viable as in the case of the ITV-navigation, i.e., seeing the ITV-navigation as spatially mapped to movement or seeing it as functionally mapped to content selection. Also, some subjects were oblivious to basic multimedia interaction techniques used in the interface, e.g., "highlighting" to show selection.

The lesson to be learned is not only that the mappings of remote controls should be logical, but that it is complex to develop non-standard interfaces. The risk of making mistakes is much higher than when developing more time-proven, standardized interfaces such as standard desktop applications with menu bars, tool bars and dialog boxes or even web site navigation. Not only is the risk of making mistakes higher because the interface is non-standard, but also because as indicated above, the user group for ITV is not necessarily on par with the average PC user with respect to understanding novel interfaces. It is easy to forget that ITV is an area of design with its own user demography.

Engagement issues and the content of the service with the simple interface

At first hand one might guess that the problems of engagement with the simple interface had to do only with the rudimentary nature of its interface. It was discovered however, that the content of the ITV service did not work so well. The content of the ITV service had been chosen so as to provide more information than was available in the TV show, e.g., it expanded on the presented subject matter. Most of the subjects were dissatisfied with the choice of content in the ITV service. The subjects did not report that the content was of low quality per se, but that it was unfitting. The content did not work well although it was conceptually close to the TV show. This might seem paradoxical. There is, however, a simple explanation for why the subjects reacted the way they did to the ITV service content. During interviews it became clear that the subjects wanted a particular kind of "content nearness". This nearness can be summarized (for want of a better expression) as TV show concrete nearness. Such nearness can be distinguished from TV show conceptual nearness. Something is concretely near to a TV show if it brings up and elaborates on the concrete things, settings or people within the TV show. So if a person is depicted in a TV show as "John the houseboater" on his houseboat, then content that is concretely near would involve John and his houseboat. In contrast, content that is conceptually near would not have to treat of John the houseboater or his houseboat. Conceptually near content could simply treat of houseboating in the abstract or other houseboaters and/or houseboats. The subjects in the show were generally in favor of content that manifested concrete nearness and they only advocated bringing in content manifesting conceptual nearness if it was particularly valuable (i.e., contact information, and pointers to further information). One way to summarize this is to say that in absorbing the content of the ITV service, the subjects were more willing to make concrete associations to the particulars of TV shows rather than engage in abstract or conceptual associations.

Concrete and conceptual nearness will let the viewer accommodate more easily to the ITV service since little is demanded mentally to do so. The viewer accommodates mentally to the TV-show, the ITV-interface and the ITV-content in unison. In figure 2, optimal accommodation is predicted to occur in the first quadrant, we may call it the accommodational quadrant. It is only in this quadrant that the ITV service elements are both concretely and conceptually near. We realize that no final conclusions can be drawn from this study regarding the importance of concrete and conceptual nearness. We hope, however, to in some small way suggest how usability can be thought of as being dependent on factors that have to do with the content presented with an information tool rather than the tool itself. Why the subjects reacted the way they did regarding the content of the ITV service need to be investigated in future studies.

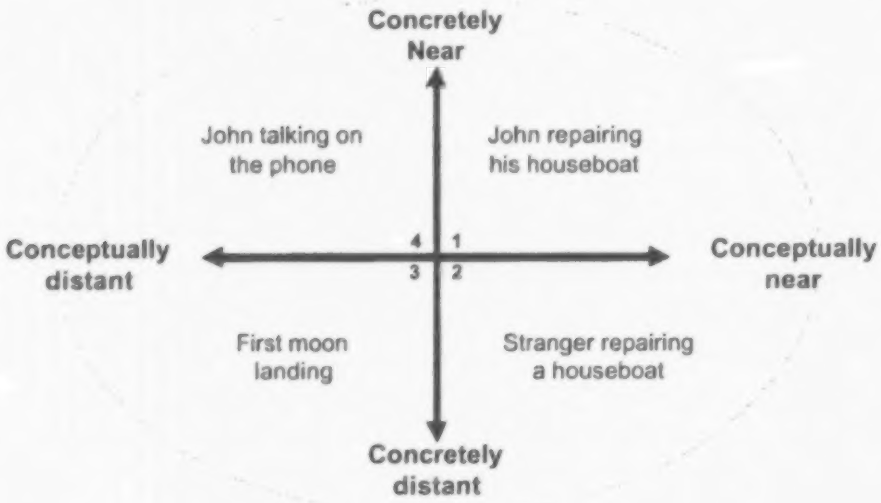

Figure 2: Concrete and conceptual nearness for a TV show about John the houseboater.

Conclusions

We suggest a way to make ITV services more attractive. The traditional approach has often been to include various appealing graphics (Westerlink 1998). Our suggestion, however, is that careful attention not only be given to the appearance and metaphorical meaning of included graphics, but that included graphics be evaluated in terms of concrete and conceptual nearness. When using place-like interfaces for DTV, the buttons on DTE remotes should be mapped carefully to avoid cognitive dissonance between, e.g., user beliefs about navigation and item selection. However, DTE remotes have limited sets of universally usable buttons (across hardware) and designers may be tempted or even forced to design cognitively dissonant use schemas. Furthermore, it is unsafe to rely on basic multimedia interface techniques in DTV interfaces as many users seem to have considerably difficulty with them. In the final analysis, we acknowledge the difficulty of designing novel media rich interfaces, and the need to establish good usability as fundamental.

If our conclusions are correct with respect to concrete nearness, which further investigations would have to decide, then the implications for ITV educational television are important to consider. We have not treated of learning in the traditional sense, e.g., in terms of retention and recollection, much because of our limited knowledge of the subject. The results presented here point to a way of making a more positive impact on the learners' attitude to ITV information services for distance education. By treating the content of an ITV information service as being subject to blending, through concrete nearness, with the TV show, the ITV information service can be received as more interesting, enjoyable and meaningful. In sum, we have arrived at a suggestion for a tripartite agenda in developing and ITV information service: (1) to put usability first and make early usability studies, (2) choose content which is concretely near to the TV show at hand and, if time and the budget at hand permits it, (3) experiment with novel interfaces for even more engaging learning experiences.

Abstract: Current training strategies implemented in online WBT training sessions are rather simple strategies. They lack a number of aspects of typical classroom training strategies, such as composite training strategies, possibility to customize and adapt training strategy, collaborative training strategies, and so on. In this paper we present a novel WBT tool called Virtual Classrooms, which we implemented to support such aspects. By doing so we wanted to mirror at least a small part of the typical classroom experience onto online training sessions in a WBT environment. Virtual Classrooms are implemented as a part of the modern WBT system called WBT-Master.

1. Introduction

From the users' point of view WBT systems deal with online training sessions. Learners (students) are participating in different training sessions, whereas teachers (tutors, authors) are preparing and conducting those training sessions.

Conceptually, a WBT training session consists of a number of training objects and a particular training strategy (Helic et al., 2000; Helic et al., 2001a; Helic et al. 2002). Training objects might be learning courses, learning goals, discussion forums, etc. On the other hand, a particular training strategy reflects a particular way of working through the subset of training objects to achieve a particular training goal. Such a training strategy might be considered as a certain training methodology.

Technically, a training methodology is implemented as a collection of WBT tools combined to support the desired way of working with the WBT system (Helic et al., 2001a). For example, consider the basic WBT training strategy known as Web-based learning. This training strategy is a collection of WBT tools, such as simple navigation links (prior/next/up), course maps, course syllabus, etc. Those tools provide functionality needed to work with simple WBT learning courses, i.e., to access, browse, navigate, and read through such courses (Dietinger and Maurer, 1998).

All WBT systems support at least the basic WBT training strategy, but usually they also support a number of more advanced strategies.

For example, e-Learning Suite (Dietinger and Mauerer, 1998) supports a training strategy called organizational learning (Malone et al., 1999). Organizational learning is supported by sophisticated WBT tools, which provide the access to the so-called Corporate Memory (Abecker et al., 1999; Ackermann, 1994), made up of information that is found within a company in the form of not only learning courses, but also other documents, discussion forums, etc.

Another advanced WBT system, WBT-Master (Helic et al., 2000; Helic et al., 2001; Helic et al., 2001a; Helic et al. 2001b; Helic et al., 2001c; Helic et al., 2002), supports a wide range of different WBT training strategies, such as Web-based tutoring (Helic et al., 2001a) (tools leading students through a sequence of learning actions to a particular learning goal), Web-based mentoring (Helic et al., 2001a, Helic et al., 2001c) (tools supporting synchronous online mentoring sessions), and so on.

Obviously, WBT systems that support not only the basic Web-based learning, but also a number of advanced online training strategies can be much more effective in an online learning process. Let us just consider the following simple example. Suppose a WBT tutor has two groups of students and WBT-Master system installed in his organization. The students from the first group prefer to work with the learning material in some kind of a "guided tour", i.e., they prefer if the tutor leads them through the learning process by pointing out what to do at each step of the learning process. Thus, for the first group of students the tutor might conduct a training session supporting Web-based tutoring strategy. On the other hand, the students from the second group prefer to work with the learning material in a more free and associative way. Thus, this group can be the subject for Web-based learning strategy.

If we compare advanced WBT systems with more typical ones (that just support Web-based learning) we may see that the advanced ones provide at least more flexibility in choosing a particular training strategy for online training sessions.

Usually, advanced WBT systems provide even more (Helic et al., 2001a): synchronous/asynchronous communicational facilities, collaboration tools, sophisticated customization mechanisms, progress tracking, etc. These facilities tremendously improve not only the overall quality of the conducted online training sessions, but also the experience of all participants (learners and teachers) of these sessions.

Nevertheless online training sessions still lack a number of important aspects of any typical classroom session (Plagemann and Goebel, 1997; Simoff and Macher, 2000; Schneidermann et al., 1995). Let us mention here just a few of these aspects.

A training strategy in a classroom session can be composed of a number of more simple training strategies. Such simple training strategies can be combined in a number of ways: they can be applied at the same time, in a time sequence, etc. For example, a classroom training session on object-oriented programming might start with the lecture on object-oriented programming concepts (the first training strategy) and then move over to students having to write an object-oriented program and apply the concepts from the lecture (the second training strategy).

Moreover, since the teacher in the classroom training session immediately gets the feedback about the applied training strategy he may adapt it accordingly. Thus, the classroom training strategy is not only a composite (heterogeneous) strategy, but it can be also adapted, or even extended on the fly. On the other hand, particular training strategies in online training sessions are rarely composite, but rather they are simple and atomic.

Usually, we can just select one of such simple atomic (Web-based learning is an example of an atomic online training strategy) training strategies from the strategies that are supported by the system in order to conduct our training sessions. Even if we have the possibility to pick an advanced training strategy (such as Web-based tutoring, which in fact can be composed as a sequence of different more atomic training strategies) we still lack the possibility to adapt such training strategy in a synchronous manner as the result of an immediate students' feedback.

Another important aspect is the collaborative aspect of any classroom training strategy. Writing the object-oriented program from the example above by a group of students can be achieved only if all students from the group work in collaboration. Many of current WBT systems lack such collaborative aspects completely, needless to say that they lack support for a collaborative training strategy and that maybe in the scope of a more heterogeneous, adaptable online training strategy.

Obviously, supporting at least such basic aspects of classroom training sessions in an online WBT environment would improve the experience of all WBT users (Brusilowsky, 1998). Learners would be confronted with more sophisticated training strategies; they would have a possibility to work in collaboration with other learners, and they would have a feeling that they are being "heard", since the training strategy adapts to their needs. Tutors would not be restricted to a certain simple training strategies, but they would have the possibility to create sophisticated, customized training strategies, which can be adapted in the real time to students' preferences. Thus, they would obtain more freedom in implementing their training sessions.

We implemented a simple WBT tool called Virtual Classrooms that support the above aspects and try to mimic as closely as possible a typical classroom training session in a WBT online environment. This tool is a part of the advanced WBT system: WBT-Master.

2. Virtual Classrooms Concept

Conceptually, WBT-Master Virtual Classroom is a special synchronous/asynchronous collaborative training and working environment. A Virtual Classroom provides all necessary tools for both tutors and learners that they need to conduct training sessions with highly sophisticated, adaptable, extensible and collaborative training strategies.

Usually, a tutor creates a single Virtual Classroom to support an online training session. The created classroom comprises:

- All training objects that are needed to conduct the training session.
- All WBT tools that reflect the particular (usually composite or heterogeneous) training strategy for that training session.
- All communication/collaboration tools needed for collaborative synchronous/asynchronous work.

Virtual Classroom allows the tutor to use any kinds of WBT-Master training objects (i.e. courses, goals, documents, even other classrooms, etc.) available in the system. Further, both the tutor, as well as the learners may upload local files and use these files as training objects in that particular training session. Also, the tutor may remove training objects from the Virtual Classroom.

A particular training strategy is reflected through the kind of training objects that the tutor provides for the learners. Thus, whenever the tutor selects a training object for the training session the system automatically recognizes the type of that training object (e.g. learning course, learning goal, etc.) and provides all the tools that are necessary to work with that training object. For example, if the tutor selects a simple learning course, all navigational tools such as course map, course syllabus, etc. are immediately available for the learners, thus reflecting Web-base learning strategy. Similarly, if the tutor selects a learning goal all tools needed to guide the learners through the sequence of the learning actions contained in that goal are automatically available, thus reflecting Web-based tutoring strategy. Since, any number of training objects may be inserted into the Virtual Classroom the tutor may in that way create rather composite and heterogeneous training strategies. The adaptability and extensibility is guaranteed in the way that the tutor may add, even remove training objects from the created Virtual Classroom at any given time.

At all times the learners may see the tutor and other classmates presence, communicate via the special messaging mechanism or work together on a certain document.

3. Virtual Classrooms in WBT-Master

Technically, Virtual Classroom consists of the following components (see Figure 1):

- *Virtual Classroom Library* is a collection of WBT-Master training objects selected for the particular training session. As we already mentioned training objects of any type may be selected for such classroom library.
- *Training Curriculum* is a description of the training session. The curriculum explains what actions should be performed by learners and in which sequence. Thus, the curriculum can be also seen as the starting training strategy of using the resources and classroom tools for achieving a particular training goal. Of course, as we already mentioned at any given time the tutor may adapt or extend this training strategy.
- *Classroom Locker* is a repository of materials (i.e. files) uploaded to the WBT-Master server by users working with this particular Virtual Classroom. Obviously, the Classroom Locker is a shared repository in the sense that users may upload their local files and/or references to existing Internet resources (URL) to make them available for other users. The locker might be seen as the primary tool for collaborative learners' work.

- *Classroom Forum* is a sequence of messages (on-the-fly contributions) made by the learners of the virtual classroom. The classroom messages may refer to files/references previously uploaded to the classroom locker.
- *Classroom Blackboard* is a special window where a currently selected training resource is visualized. The Classroom blackboard may be individual or shared. In case of an individual blackboard, the learners are free to select any of previously defined training resources and/or elements from the classroom locker to work through on such individual blackboard. In case of the shared blackboard, the classroom tutor may select training resources and files for all participants of the classroom. The blackboard (especially the shared blackboard) may be seen as the primary tool applied in order to adapt the training strategy, since the tutor may receive an immediate feedback from the learners in a synchronous manner. Of course, the forum might be used all the time for providing the feedback in a more asynchronous manner.

DDL Notation

This training unit provides a presice introduction to a Relational DDL

Learning Unit: reldb/rdb1.cif

Figure 1 : Virtual Classroom without a blackboard

User interface solutions in Virtual Classroom tool are rather simple and intuitive. For example, the classroom library is displayed as a list of items. Clicking on a particular item in that list results in activating a new blackboard window, which allows working with this particular training object.

Once when the blackboard is activated the set of tools needed to work with that type of training object is automatically provided for the learners. Thus, if a learning course is selected all tools associated with learning courses are displayed (see Figure 2). In that way it is guaranteed by the system that a particular training strategy that the tutor had in mind is actually implemented.

In the case of the shared blackboard the tutor gets additionally few tools for synchronous communication with the learners. For example, the tutor may use a special pointer to point to certain areas on the screen and write additional comments on that pointer.

Note that similar synchronous communication mechanisms are available for the learners all the time. Thus, they may at any given time obtain information about the online presence of other learners, send them messages, or comments to documents that they are working together, and so on.

Figure 3: Creating the classroom curriculum

BEST COPY AVAILABLE

An additional administration screen is provided for the tutor. Basically, the tutor works all the time just with the curriculum and classroom library. Thus, at the beginning of each training session the tutor creates the starting curriculum and selects a number of training objects for that curriculum. As the training session progresses he might need to modify the curriculum and/or the classroom library. The administration screen allows the tutor to do so (see Figure 3).

Another interesting aspect of the administration subsystem is the possibility to export and import virtual classrooms. For example, the tutor wants to move a very successful Virtual Classroom from one WBT-Master server to another one. Thus, the tutor exports the Virtual Classroom from the first server (all training objects, the curriculum, etc. are exported) and imports this Virtual Classroom into the second server. All needed information is restored on the second WBT-Master server.

Lastly, since WBT-Master supports a highly sophisticated user access control mechanism the tutor may define the access rights for all the learners by using the administration subsystem.

4. Conclusion

We saw that a Virtual Classroom provides an integrated working environment for all of its participants.

The tutor may create a Virtual Classroom with particular training objects and a particular training strategy for any training session, which he/she is going to conduct. Typical example would be a special organization offering training sessions on a contract basis. Each employee of such training organization may be provided with a special virtual classroom where he/she would define a particular classroom library of training objects by selecting from a big repository of training objects accumulated by the training organization of its main assert. Taking into account, a particular customer's training request the tutor may also define a very special classroom curriculum for this customer.

On the other hand, the learners participating in the Virtual Classroom are provided with all tools needed not only to work through the selected training objects, but also with tools that allow them to communicate with other learners and to work together with them on certain documents. Thus, by working in such Virtual Classroom environment the learners are provided with a strong classroom feeling.

How University Faculty Assess Scholarly Use of the Internet

Paul David Henry, Ph.D.
Program House
pdhenry@programhouse.com

Abstract: This quantitative survey of university faculty tested a theory of status-related risk by examining the affect of three organizational statuses on the use of this educational innovation. It also explored how use is mediated by assessment of risks to their professional perquisites. Academic field and computer-based specialty statuses were moderately correlated with Internet use. Computer-based specialty as an indicator of prior knowledge and experience was also correlated to use while controlling for assessment of risk. Thus, there was some overall support for a status-risk theory in the relationships between use and both status and risk assessment. Overall, this study shows that faculty attribute Internet use with generally positive impact on scholarly work, especially as it contributes to greater scholarly exchange of ideas.

Introduction

The faculty experience for those who seek to study and teach online is a path paved with change. Measured against the history of educational innovations, scholarly use of the Internet by faculty is in its infancy, despite its rapid growth from a government-sponsored boost for academic research in the late 1970s to the rise of online courses, online learning communities, e-journals, and virtual universities within two decades. The novelty and complexity of these educational innovations are associated with some uncertainty and a need to assess individual investment against risk - for with individual commitment to change comes both risk and (hoped for) benefit. As reflected in the Confucian adage "only the wisest and stupidest of men never change," there is no change without risk, but many will risk not changing - at least when and where the risk seems greatest.

As educational research and practice continue to reveal, learning has a social and organizational dimension - whether or not the meeting of minds is achieved through media such as the Internet. The fulcrum for this change can be found where individual aspiration and this social and organizational framework meet. Measuring attitudes and behavior of individual faculty within this context can reveal what otherwise lies hidden beneath change and may inform those seeking greater adoption and use of this new medium for scholarship. This paper summarizes findings from a quantitative survey of faculty in a research university setting that tested a theory of status-related risk in an attempt to understand why some faculty may be using this new medium more than others. In the context of viewing faculty as models for online scholarship, it seemed practical and timely to study how they have been using this new medium for that purpose.

A typical university with its schools, departments, and programs and the administrators and faculty is an example of a stratified, hierarchical social structure (Bess 1982). Despite the principle of academic freedom afforded by previous innovations, such as tenure and peer-based review, there are clear norms interpreted by administration and peer committees. These norms largely equate tenure, promotion, and considerations of faculty duties and schedule to evidence of research and publication productivity (Schweitzer 1989). With faculty reporting decreasing amounts of time for performing their varied duties, there may be diminishing time for research or the social and collegial contact that stimulates and refines the development of ideas (Creswell 1986).

Although some social and collegial contact can be achieved through traditional communications, there is still the challenge of disseminating knowledge or publishing results of research. This important component of scholarship is daunting to junior faculty as they are subject to the traditional academic reward system of "publish or perish" (Carnegie Foundation 1989). Despite its potential to overcome many of the limitations

BEST COPY AVAILABLE

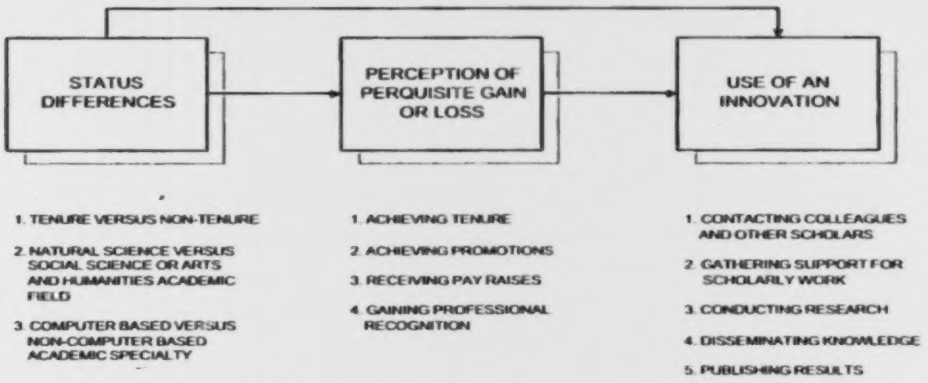
of traditional communications, the use of network communications still poses risks to faculty who try to use an innovative and formally unrecognized medium for scholarly publication, especially if it is submitted for faculty evaluation (Martin 1992; McNulty 1995).

Theoretical Framework

This study employed a theoretical framework that previously has shown promise in understanding aspects of receptivity to organizational innovations. This theory is known as the status-risk theory of receptivity. As articulated by Giacquinta (1975a, p.42), it predicts that organizational and non-organizational statuses are basic in determining member receptivity to innovations within an organization. His status-risk model posits that: "1) all innovations contain varying degrees of possible benefits, risks, and uncertainties for organizations and organizational members depending on their statuses, and 2) that organizational member receptivity is a function of the extent to which he perceives risks, and more specifically of the degree to which he perceives direct or indirect risks to the perquisites accruing to his organizational status, were the innovation to become a reality."

Giacquinta's initial test of this theory was based on educator reactions to the proposed introduction of sex education into elementary schools (Giacquinta 1975a). His findings on differences in degree of receptivity confirmed the prediction for the four statuses that he studied: (from least receptive to most receptive) board member, administrator, teacher, and specialist of sex education.

This study took status risk theorizing in a different, though related, direction: the *use* of innovations by organizational members. Three academic organizational statuses were examined based on their importance in previous studies of faculty research performance (Creswell 1986): faculty tenure, academic field, and computer-based versus non-computer-based academic specialty. The basic model (Fig. 1) examines the following relationship among variables: an independent variable of status differences which influences both the intervening variable of perceived advantage or disadvantage to perks and the dependent variable as use of network communications in scholarly work.



STATUS DIFFERENCES
PERCEPTION OF PERQUISITE GAIN OR LOSS
USE OF AN INNOVATION
1. TENURE VERSUS NON-TENURE
2. NATURAL SCIENCE VERSUS SOCIAL SCIENCE OR ARTS AND HUMANITIES ACADEMIC FIELD
3. COMPUTER BASED VERSUS NON-COMPUTER BASED ACADEMIC SPECIALTY
1. ACHIEVING TENURE
2. ACHIEVING PROMOTIONS
3. RECEIVING PAY RAISES
4. GAINING PROFESSIONAL RECOGNITION
1. CONTACTING COLLEAGUES AND OTHER SCHOLARS
2. GATHERING SUPPORT FOR SCHOLARLY WORK
3. CONDUCTING RESEARCH
4. DISSEMINATING KNOWLEDGE
5. PUBLISHING RESULTS

Method

A survey research design was chosen as the approach to study the use of network communications among faculty. A short, self-administering questionnaire was used to measure such uses and statuses. The need for basic, self-descriptive information from many faculty to test a theory involving their use of network communications, perceptions of risk, and statuses could not have been met by other basic empirical methods such as a controlled experiment or face-to-face field work.

The setting selected for the study was a large, eastern university with a national reputation as a research institution. Its large size, number of schools, students, and its faculty with diverse academic statuses satisfied the need for data in this study. Subjects were selected from a sampling frame composed of all full-time, tenured and non-tenured (but tenure-track) faculty. In this setting, all full-time faculty were automatically issued accounts that allow computer and network access.

Faculty from four schools within the university were included in the sample. As school affiliation was initially defined as an important variable and a source of status in this study, comparison of equal numbers of faculty was important. To do this, a stratified, disproportionate random sampling design was adopted. The sample size was based on the school with the smallest number of faculty (n=67). Drawing a random sample of 67 faculty from within each of the other three schools provided a total sample of 268 faculty.

Findings

The theoretical focus of this study was primarily concerned with a group of three paired hypotheses that tested the efficacy of the status-risk theory in predicting the use of this innovation by selected statuses. To test this model, four relationships were tested: status and use, status and perquisites, perceived advantages and use, and the relationship between status and use by controlling for perceived advantages. The following descriptions and corresponding tables present the findings from each of these four analyses. Each of these hypotheses predicted that subjects possessing one status within a grouping would use network communications for a given scholarly activity more than those with the contrasting status in that grouping.

Hypothesis 1a predicted that tenured faculty would make more use of network communications for publishing results of scholarly work than non-tenured faculty. Hypothesis 2a predicted that natural science faculty in this study would make more use of network communications for contacting colleagues and other scholars, gathering support for scholarly work, conducting research, disseminating knowledge, or publishing results of scholarly work than social science faculty or arts and humanities faculty. Hypothesis 3a predicted that faculty in computer-based academic specialties in this study would make more use of network communications for contacting colleagues and other scholars, gathering support for scholarly work, conducting research, disseminating knowledge, or publishing results of scholarly work than faculty in academic specialties that are not computer-based.

Pearson product-moment correlations (Tab. 1) were made between the use of network communications for the five scholarly activities and globally with the three sets of faculty statuses: tenure vs. non-tenure, academic field (natural science vs. social science and arts and humanities), and computer-based vs. non-computer based academic specialty.

Tenure was not correlated globally or with any of the five scholarly activities. Thus, Hypothesis 1a was not confirmed. However, moderate correlations between academic field and the five scholarly activities as well as global use of network communications confirmed Hypothesis 2a. Similar correlations were found for computer-based specialty, which confirmed Hypothesis 3a.

Pearson Correlations of Network Communications Uses With Selected Status Characteristics of Faculty (n=141)

	Tenure	Academic Field	Computer Specialty
Contact Colleagues	-.15	.30***	.25**
Gather Support	-.10	.28**	.30***
Conduct Research	-.13	.33***	.33***
Disseminate Knowledge	.04	.41***	.40***
Publish Results	.02	.28**	.27**
GBLUSE	-.11	.36***	.35***

Note: GBLUSE represents overall use of network communications across scholarly activities.

*** p <=.001
** p <= .01
* p <= .05

Table 1: Correlations of Network Communications Uses with Faculty Status Characteristics.

Another aspect of status risk theorizing led to three other hypotheses. Hypothesis 1b predicted that compared to tenured faculty, non-tenured faculty would consider network communications for publication of the results of scholarly work to be less advantageous for achieving tenure, achieving promotions, receiving pay raises, or gaining professional recognition.

Hypothesis 2b predicted that natural science faculty would perceive the use of network communications for contacting colleagues and other scholars, gathering support for scholarly work, conducting research, disseminating knowledge, or publishing results of scholarly work as more perquisite-enhancing (i.e., achieving tenure, achieving promotions, receiving pay raises, and gaining professional recognition) than would social science faculty or arts and humanities faculty. Hypothesis 3b predicted that faculty in computer-based academic specialties would perceive the use of network communications for contacting colleagues and other scholars, gathering support for scholarly work, conducting research, disseminating knowledge, or publishing results of scholarly work more as more perquisite-enhancing (i.e., achieving tenure, achieving promotions, receiving pay raises, and gaining professional recognition) than would faculty in academic specialties that are not computer-based.

To reduce the complexity of this analysis, two summary scales (CONSUPRES and DISSPUB) were successfully derived through factor analysis (with high factor loadings) and were then used to represent the data. Pearson product-moment correlations (Tab. 2) were made to determine whether the perceived advantages in the use of network communications were related to the three sets of faculty statuses: tenure versus non-tenure, academic field (natural science versus social science and arts and humanities), and computer-based versus non-computer based academic specialty. Tenure was not correlated with either of the two factors representing perceived advantages. Thus, Hypothesis 1b was not confirmed. However, moderate correlations between academic field and both scales confirmed Hypothesis 2b. Similar correlations for computer-based specialty confirmed Hypothesis 3b.

Pearson Correlations of Two Scales of Perceived Advantages to Network Communications Uses with Selected Status Characteristics of Faculty (n=141)

	Tenure	Academic Field	Computer Specialty
CONSUPRES	.03	.22*	.32***
DISSPUB	.13	.31***	.29***

Note: The CONSUPRES scale represents faculty contact, support, and research activities, whereas DISSPUB represents knowledge dissemination and publication of results.

*** p <=.001
** p <= .01
* p <= .05

Table 2: Correlations of Perceived Advantages to Network Communications Uses with Faculty Status Characteristics.

A further test of this theory requires that perceived advantages and network communications use should be positively related. Perceived advantages showed moderate correlations with use (Tab. 3). CONSUPRES was with one exception, somewhat more strongly related to contacting colleagues, gathering support, and conducting research as expected, whereas DISSPUB was more strongly related to disseminating knowledge and publishing results.

Pearson Correlations of Faculty Uses of Network Communications with Two Scales of Perceived Advantage (n=141)

	Global Use	Contact Colleague	Gather Support	Conduct Research	Disseminate Knowledge	Publish Results
CONSUPRES	.36**	.23	.40***	.40**	.34***	.23***
DISSPUB	.27**	.12***	.27*	.27*	.33***	.32***

*** p <=.001
** p <= .01
* p <= .05

Table 3: Correlations of Faculty Uses of Network Communications with Perceived Advantages Scales.

As a final test of the theory, the relationship between status and use controlling for perceived advantages was determined using a series of partial Pearson product-moment correlations (Tab. 4). According to the theory, perceived advantage acts as an intervening variable between status and use. If perceived advantage is controlled, the zero order correlations should drop between status and use.

Controlling for perceived advantages did lead to reductions in the size of the original bivariate correlations for the status of computer specialty. Thus, the analysis does lend support to status risk theorizing in the case of the computer specialty status. However, controlling for perceived advantages had little or no affect on the correlations for the status of academic field with any of the five scholarly activities.

Partial Correlations of Computer Specialty With
Scholarly Uses Controlling For Perceived
Advantages of Network Communications (n=141)

Status	Zero Order	Control for CONSUPRES	Control for DISSPUB	Control for both
Computer Specialty with:				
Global Use	.35***	.23**	.26**	.23**
Contact Colleagues	.25**	.17	.20*	.17*
Gather Support	.30***	.10	.19*	.14
Conduct Research	.33***	.21**	.26**	.22*
Disseminate Knowledge	.40***	.27**	.29***	.26**
Publish Results	.27**	.18*	.16	.16

*** p <=.001
** p <= .01
* p <= .05

Table 4: Correlations of Scholarly Uses Controlling for Perceived Advantages of Network Communications.

Conclusions

The results of this study add moderate support to the premise that status-risk theorizing, previously found useful in characterizing receptivity at the initial stage of planned change, can also contribute to determining use during the implementation stage. In particular, this study points to its usefulness in characterizing individual response (in the context of work) to the type of complex organizational and social innovation represented by network communications.

Moderate support was found in the relationship of status to use. Two of three organizational statuses (academic field and computer-based specialty) were moderately correlated with use of this innovation. Only one of three statuses (computer-based specialty) was correlated to use while controlling for assessment of risk. However, there was also moderate correlation between assessment of risk and use that was independent of statuses selected in this study. Thus, there was some overall support for the status-risk theory in the relationships between use and both status and risk assessment.

There are several possible reasons for the lack of variance between non-tenured and tenured faculty in their use of network communications for publishing results of scholarly work, but foremost is this shared sense of uncertainty. This may reflect the relationship between uncertainty and outcome found in other innovation studies (Cancian, 1972; Giacquinta, 1975b), where inaction and resistance would broadly characterize a predominant outcome and some degree of risk-taking reflecting another outcome. However individuals assess this or even observe and reflect changing group norms, it seems clear that both non-tenured and tenured faculty largely agree rather than differ in their cognitive assessments of the value of publishing online for tenure.

Though typical of social science studies, there was a relatively small variance explained (roughly 20%) by the testing of hypotheses. Thus, a confirmation of the findings should be sought in a replication study that would account for possible limitations in the design and execution of this study. For example, the sample was under-represented by Math and Computer faculty (67.9% of non-returners). And although males represented 66% of the original sample, when comparing return versus non-return, more females in the sample returned (68.6% of females) than males (48.4% of males). Thus, a replication of this study should consider a larger sample size and other measures to ensure a better representation of statuses.

Another area of implication in this study has to do with the variance in network communications use attributed to an individual's prior knowledge and skills in using computers. At a basic level, the significance of this factor in this study implies that an individual's prior knowledge and skills should be operationalized as an important status in studies and practices during the implementation stage of complex innovations like network communications.

Allowing that prior knowledge and skills associated with computer use in the natural science academic fields and/or computer-based specialties are not necessarily equivalent to the knowledge and skills in the related, though distinct area of network communications, some degree of transfer must be occurring to explain the relative success that subjects with these statuses had in their network communications for scholarly work.

In sum, the implications of this study are that efforts to support the use of network communications for scholarly work should explicitly recognize an individual's statuses and assessment of risk. Also, an individual's prior knowledge and experience should be addressed in the support of implementation efforts. Rather than solely providing computer equipment and training in the use of software applications, change agents should employ this social and cognitive understanding as strategies to support online scholarship.

Abstract: Carrying out argumentative discussion online has become rather common in higher education. This task is traditionally supported by asynchronous collaboration tools, but we believe that also synchronous supports could be useful. In this paper we focus on scaffolding the knowledge construction: the work of two student moderators jointly moderating a theme as part of a seminar type university level course. As a new scaffold, we describe a collaborative note-taking tool as an extension to a standard conferencing system. This new tool can be utilized either asynchronously or "semi-synchronously". An empirical evaluation of our first implementation of this tool is reported. There were almost 60 students on three courses who had an opportunity to use the tool. The evaluation shows that our students were not used to working together this way, although they recognised the benefits for joint moderating. We offer some explanations for these results and discuss our further plans in this area.

Introduction

In higher education today, there is a tremendous worldwide pressure to produce online "E-courses" that would be available for both students on-campus and those off-campus, e.g. working simultaneously with their studies. Indeed, there are currently numerous efforts underway transferring existing courses online and creating new online ones. At the same time, there is a well-recognised need to learn how to work collaboratively. Because people seem to find less and less time for face-to-face meetings, collaboration should be an essential part in E-courses, too. A vast body of research shows, however, that online cooperation and collaboration is not easy.

One emerging issue is the fact that in a well-designed WWW-based learning environment there should not be just one dominant way of communication and collaboration, but several of them – for different learners and for different teachers (Collis & Moonen 2001). In this approach, however, there is a danger that there might be too many separate tools for the learner – the richness becomes an overload. In our opinion, for the best benefit, the learner should receive scaffolding and support in choosing these facilities, and they should be "close to the task" and available "just-in-time". We agree with Erkens *et al.* (2002): "The relationship between collaboration processes, task strategies and the use of the tools and resources that the computer environment offers, may be crucial for the effects of computer supported collaborative learning."

One of the most common tools in any online learning environment today is an asynchronous conferencing facility that allows the learners to participate and contribute free from specific lecture times and free from specific physical places of education institutions. However, learning in real-time together with your teacher and peer learners should not be forgotten.

We have been working with asynchronous conferencing systems (Hietala 1999, Hietala 2001) with the emphasis on collaboration of small groups and student pairs. We have noticed that, in some learning situations, a considerable amount of student work consists of collaborative writing and planning, which would benefit from working synchronously. One tool to support this might be a collaborative note-taking tool, inside the conferencing system, that could be used in "synchronous fashion".

In this paper we report on an empirical evaluation of our first implementation of a tool of the above kind on three courses with 59 students. The students worked in pairs and the task to be scaffolded was a joint moderation where two moderators were required to moderate together an online discussion during four weeks' time. Besides normal conferencing facilities they were provided with a personal notebook within the conferencing system, which they could share with their moderator pair.

The evaluation shows that our students were not used to working together online this way, although they recognised the opportunities offered for joint collaborative writing and moderating ongoing discussion. We offer some explanations for these results and discuss also our further plans in this area.

Asynchronous vs. synchronous collaborative moderation

According to Mason (1998) there are several advantages to the asynchronous online learning, e.g.:

- flexibility - access to the computer conference discussions can take place at any time and from many locations,
- time to reflect - rather than having to react immediately, the learner is allowed to mull over ideas and prepare a comment, and
- situated learning - because the technology allows access from home and work, the learner can integrate the ideas being discussed on the course with the working environment.

On the other hand, Mason (1998) lists advantages to synchronous systems, too:

- motivation and pacing - synchronous systems focus the energy of the group, providing motivation to distance learners to keep up with their peers and continue with their studies,
- telepresence - real time interaction with its opportunity to convey tone and nuance helps to develop group cohesion and the sense of being part of a learning community, and
- good feedback - synchronous systems provide quick immediate feedback on ideas and support consensus and decision-making in-group activities.

In this paper we are interested in the task of moderating online conferences. Modern "integrated" environments, like e.g. WebCT, offer the course designer (teacher) an opportunity to include both asynchronous (bulletin boards, e-mail...) and synchronous (chats, IRCs...) discussion areas for their students. However, these are often used separately and seen as complementary. Intertwining of them is seldom suggested.

These two interaction modes seem to support different, albeit necessary working methods. Considering argumentative university-level discussions, for example, one study (Veerman *et al.* 1999) found out that in one synchronous system, students engaged into short and strong discussions. They checked, challenged and countered each other's information and produced additions and evaluations. On the other hand, in the same study, the asynchronous discussions with an asynchronous tool could be characterised as highly constructive, and students tended to argue 'mildly' by information checks and they mainly added or explained information.

However, are there situations or tasks, which would benefit from both of these two interaction types being available? We introduce collaborative moderation of online discussions as one such a task. The task we consider here is a pair of students jointly moderating a theme on a computer conferencing area. There are numerous guidelines for the moderating task (see e.g. Paulsen 1995, Muilenburg & Berge 2000), but interestingly, joint student moderation has been studied very little. A recent exception is the work by Rourke and Anderson (2002), where groups of four students were used to lead online discussion on course readings. In our work the student moderators worked in pairs, and also, they were able to utilize the content of their moderated discussion group later on when they prepared and presented their seminar paper on the very same topic they were earlier moderating.

We can distinguish several subtasks in the moderator's work: how to start the discussion (Phase I), how to keep the ongoing discussions alive (Phase II), and how to summarize and end the discussion (Phase III). We can envision several scenarios where collaboration is essential:

- In *Phase I*, the pair is required to prepare a joint statement on the topic at the beginning of the four-week discussion period. Bonk and his colleagues (Hara *et al.* 2000) have recommended and studied this kind of an instructional method, which emphasises the starting of the discussion process (starter-wrapper activity). Their analysis shows that student electronic comments in the discussions were highly dependent on the directions of the discussion starter – the initial posting. In collaborative moderating the pair must build joint initial understanding of the topic and compose a thought-provoking initial statement for the discussion group. Although our pairs received material and guidelines concerning their task and they had time to familiarize with the topic, we assume that still much two-way communication would be required here.

- In *Phase II*, there is an obvious need for some kind of scheduling and deciding who will answer each question or comment on a specific issue raised by the discussants in the group. Good questions are essential as part of the starting contribution, but good follow-up questions are also needed to maintain the online discussion. Moreover, there is the crucial question when to bring in new material and links to boost a weaker-growing discussion? Furthermore, building a joint understanding requires a fair amount of communication between the moderators. We believe all this calls for either synchronous or "semi-synchronous" online meetings between the moderators.
- Finally in *Phase III*, wrapping up the findings and conclusions of the discussions is required. Clearly, writing a reflective summary of the contributions resulting from online discussions of several weeks in a discussion group calls rather naturally for joint planning (asynchronously and synchronously). In our seminar course, to motivate the pair, they were given the possibility to use this summary as part of their seminar paper for their standard face-to-face seminar presentation.

To sum up, we believe that, in a task like this, there is a need for a just-in-time facility for "synchronous" collaboration within an asynchronous system. Other tools could of course be used, e.g., e-mail, chat, telephone, face-to-face meetings, but we wanted to provide one tool in line with the actual authentic discussion task and conference area. We hypothesized that here e-mail might be too slow, and chat might be too cumbersome. Placing a new facility "very close" the actual work area – the commenting area – we believe this could yield many benefits for the learning process, e.g. in the opportunity for sustained preparation of joint statements (needed as part of the moderators' work).

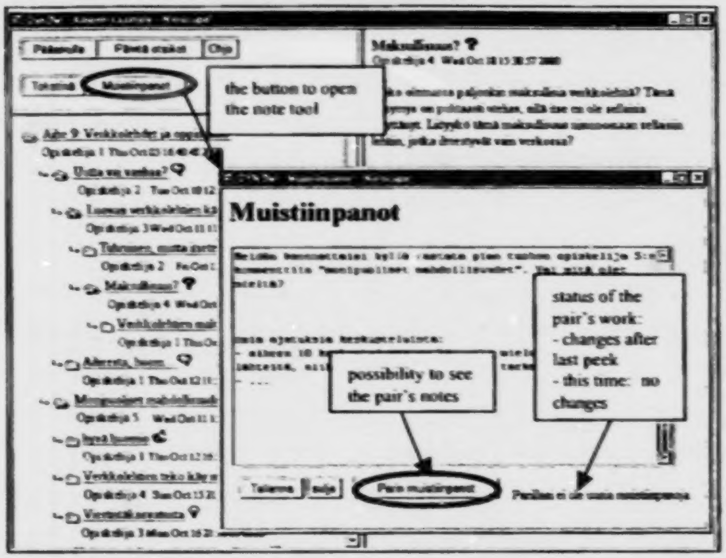
The Study

In this section we first outline the conferencing system within which we implemented the new tool and after that describe the use of this tool on our courses.

Collaborative note-taking tool

The CoWoGLe (Conferencing on the Web for Group Learning) project at the University of Tampere investigates the use of Web-based lightweight conferencing systems especially as part of university level course work. Earlier courses using our systems have been reported in Hietala (1999, 2001). Recently, some of our students raised the issue of the need for a note-taking tool inside our conferencing system. In considering this, we decided that the tool could also be a shared one, thus allowing the pairs to collaborate almost "in real-time".

The new note-taking tool was available for each of the students all the time he/she was using the conferencing forum. It was possible to copy onto it parts of the discussion entries of the others, write one's own ideas, edit them and save them for further use (giving extra time to reflect). We call this *Mode A* of utilizing the note tool. Besides helping to remember, to think, to clarify, we believe that the tool can help to share: either asynchronously, or semi-synchronously. We call these two ways, Mode B and C. In *Mode B*, the pairs would leave messages to their partner onto the note area, and see and answer to that at a time that would suit them best. In *Mode C*, the pairs would decide a time when they should both be present at a networked computer, and then exchange ideas and maybe reach decisions by adding them onto their personal note areas and letting their partner see that and respond to that ("semi-synchronously"). In our system this was supported by indicators of the notes made by the pair of the student: whether they had been changed after the last peek, and also a possibility to have a look at them (see Figure 1).



Muistiinpanot
the button to open the note tool
status of the pair's work:
- changes after last peek
- this time: no changes
possibility to see the pair's notes

Figure 1: The note-taking tool, with the possibility to collaborate and to see the notes of your pair.

The Courses

Next we describe our data from three undergraduate level courses where the students were given the opportunity to utilize the note-taking tool as part of producing their Web discussion and moderation postings. The course is titled "Internet based learning environments" (all students had earlier completed our basic course on Instructional Technology). There were a few lectures to start the course, followed by the work on the Net and finally traditional face-to-face seminar sessions. At the beginning of the course the students chose a seminar topic either provided by the teacher or suggested their own one. The seminar work was conducted in pairs, which were formed by the topic selection process. The "matching" of pairs was entirely carried out on the Web - we hoped that similar interests brought them together. Next, students conducted a four-weeks online moderating of the discussion in their topic after which they presented their seminar paper in a one-hour session before the entire class.

We ran three courses of the above format in Autumn 2001 and Winter 2002. On these three courses there were altogether 59 students: 34, 9 and 16 respectively. In the following, we call these three courses as follows: The Distributed Course, The Local Course, and The Open University Course. The Local and the Open University Course students (basically) came from Tampere area and could easily work in the same computer classrooms. The Local Group consisted mainly of regular Computer Science undergraduates, although there was also one student mastering in the English Language and one vocational level in-service teacher. The Open University Group was more heterogeneous, these students were older, worked daily and attended the course at evenings or weekends.

On the other hand, The Distributed Course was a little bit different. The lectures were the same but were given at these two different locations (Hämeenlinna and Tampere, 100 kilometers apart). The group of 34 students in this group consisted of 17 in-service teachers (from Hämeenlinna) and 17 university students (from Tampere). Each moderator pair consisted of one in-service teacher and one university student. The in-service teachers mainly taught at elementary level, although there were a few mathematics teachers at secondary level. The university students were mostly computer science majors, with 20 % of them majoring to become mathematics teachers.

Table 1 depicts the corresponding discussion activity in the three groups during the four-week online discussion period. Each participant was required to produce one posting in three conference topics during each week: one moderating comment in his/her "own" topic (the one he/she would make the seminar presentation) and two in two topics that he/she had committed him/herself as a commentator. These kinds of requirements are common in order to ensure equal participation and even distribution of comments on discussions lasting for many weeks. So the minimum number of comments in our courses for each participant was 12. As we can see in Table 1, most students contributed more.

We can see from the Table 1 that the Open University students were most active and produced most postings onto the discussion areas, while the Local and Distributed Groups were almost the equal with this respect. As moderators, the Distributed Group was clearly behind the others.

	Distributed	Local	Open Univ
Number of students	34	9	16
Total number of comments	710	187	370
Average number of comments/student	20,88	20,78	23,13
Average number of comments as a moderator	6,21	8,56	8,5

Table 1. The amount of Web discussion on the three courses

Results

Our main interest in this paper is the use of the note-taking tool. We wanted to find out how the students acted in the three phases and three modes we outlined earlier. During the lecture part of the courses, the conferencing system was briefly introduced (as well as the new facility for note-taking). Students were also given a paper leaflet describing the conferencing tool.

We collected data mainly in two ways: logging the actual use of the tool, and posing a questionnaire at the end of the course. Let us first have a look at the log data. In Table 2 we have counted the use of the different functionalities present in the Note-taking Tool window (cf. Figure 1): opening and closing the tool, saving the contents of the tool, and looking at the notes of one's pair. The first three actions above give indications if the students actually made use of the tool and the fourth tells us whether the tool was used for collaboration. The student has to save his/her notes on the tool area, before his/her pair has a chance to see that there has been a change in the contents of the notes (cf. Figure 1, indicator at the lower right-hand corner). Thus the amount of the saves can be seen also as part of the collaboration.

	Distributed	Local	Open Univ
Number of pairs	17	4	7
Average number of openings/student	3,09	8,38	8,21
Average number of closings/student	1,41	6,25	4,79
Average number of savings/student	0,35	0,86	2,36
Average number of looking the pairs' notes/student	0,9	4,75	3,36
Percentage of students who did not use the tool at all	23,5%	37,5%	25%

Table 2. The use of the note-taking tool on the three courses

In Table 2 we concentrate on the pair work, so we have excluded those students from it who had to work alone. There are a few small figures in Table 2, because of the fact that in all groups there were quite many students who did not use the tool at all. However, they have been included into Table 2 figures to give a more comprehensive picture. Overall, the Distributed Group did not utilize the tool as much as the two other groups. One reason for this might be that for them both the Web-conferencing and the partner was a new acquaintance. The two other groups were more "local" and more experienced in Web-conferencing. In an unfamiliar and new situation, a learner might rely more on communication methods that one is familiar with, say, on e-mail and telephones. It takes a lot of energy to start using a rather new facility in a situation where also other tasks are resource demanding, e.g. the moderating and preparing for the seminar talk. Finally, the Distributed Group consisted of pairs where one member was typically older than the other, so the age-difference might have had an influence.

A closer look at the data shows that in the Local Group there was one student who used the tool very much and in a group as small as this (only 8 students) it will give a rather distorted outcome. This leaves the Open University Group having the most use for the tool. This might be a consequence of a closely-knit group or from the fact that they also had suggested most topics of their own. These might have motivated them to take care of the discussions more (see Table 1).

Considering the log data from the point of view of the task itself, we can say that students used the note tool almost only for moderating the ongoing discussion (Phase II). They made some notes, discussed with their partner about distribution of work and new ideas and so on. It seems that these students liked to use the tools, which are available at the same place with their ongoing work. This might also explain why students did not use the tool in Phases I and III. In Phase I the discussion hasn't yet started, so they are preparing their initial contribution with other tools. In Phase III, the discussion has come to an end, so they might have preferred here also other text processing facilities to make conclusions of the moderated discussion. The contributions of Phases I and III are also different from those of Phase II in that that they are typically longer and might need more time to prepare.

As for the "modes" of using the tool, our students found the tool most useful in supporting individual work (Mode A). In every group there was at least one pair who employed the tool for asynchronous collaboration (Mode B), the Open University Group leading also in this. However, the log data shows that no pair used it "semi-synchronously" (Mode C). One reason for this might be that our current conferencing system did not support awareness about co-learners, which in fact made it impossible for a student to know whether his/her pair is inside the system at the same time. A facility of this kind would be essential in semi-synchronous collaboration.

Opinions of the students

In all three groups about a quarter of the students did not use the tool at all (see Table 2). In the questionnaire most common of their explanations was that "I did not remember that there was such a tool". A few said "I prefer the e-mail" or "I rather do my notes using the text editor on my computer". It seems these students employed the conferencing system from their own computer at home. So they did not have actually any use for notes within the system because they used the same computer all the time. One student brought up an interesting issue - the issue of privacy: "I did not use the tool, because I wanted privacy into my communication with my pair. The teachers are able to read our notes if made using the tool". This is something the teachers should consider when teaching online. The supervising and monitoring of each student should also be visible for the student. In this way, students can themselves see, how the teacher monitors their actions and it hopefully helps them to trust the system.

Those who had employed the tool brought up similar issues that we had envisioned earlier in this paper. E.g. "I used it as a scrap board where I had several bits and parts which I used later on in my contributions" (Mode A of utilizing the tool). A few of those who had preferred the tool said that their partner's unwillingness bothered them: "I myself did not use it to anything else than having a peek at my partner's texts. He did not write anything", or "... I could have used it to give messages of my plans, so that we did not have to use the e-mail all the time". This supports our view that the students should have many tools at their disposal for successful collaboration. Indeed, they don't have to use all of these tools, but they are given an opportunity to choose those tools, which are most appropriate for their needs.

Concluding remarks

Our data seems to suggest that on-campus students used the collaboration tool more than those off-campus. We think this has to do with the nature of collaboration: it is beneficial if you "know your partner", i.e. you have seen your collaborator at least at the beginning of the course. Indeed, our tool was used most in the Open University group, who had been together on other courses, and had better familiarity of their fellow students.

Several students reported that they find the note-taking tool sensible and used it in their private work, and would have used it collaboratively if their partner had used it. Also some students, who worked alone, mentioned this issue. So, as in all group work, certain decisions and compromises are made. In our case, it seemed that most of our students a tool (telephone, e-mail) more familiar to them.

This study raises improvement ideas that we will be implementing into the next version of the note tool. We believe that it would help the collaboration if one were able to know whether his/her partner is online at the very same time. We think that there should be "pair awareness" indicators in the system along the lines of Koivunen (2002) to support the collaborative moderating process. This could benefit especially the users of the note tool when they work in the semi-synchronous fashion (mode C).

In some situations learners' virtual communication is a must, and at least in those situations in our opinion it is good for the learners to have options in their virtual collaboration. However, as our study shows, older and "safer" options are often utilized whenever possible, and there are also other, equally important ingredients in good collaboration than technology. By this we mean group-forming, preferences of the members of the pair and so on. According to our study, these issues seem to influence equally or more to the success of group work than the computer tools.

Abstract: Many concepts, methods and technologies regarding computer supports in collaborative learning environments have been proposed. We believe that it is important to take into account human relations in collaborative learning environments, where personality plays a central role. However, it is not easy to build human relations in WBE, because there are some problems in computer mediated communication. To overcome such problems, we propose the concept of personality information for awareness (PIA, for short), which represent information for self-awareness/analysis, self-disclosure, person awareness/analysis and person perception. We are designing a PIA-based system, called "PIAGETS (Personality Information for Awareness applied to Group learning in web-based Education/ Training Support system)", which supports human relations building for collaborative learning in WBE. In this paper, we report with focus on sub-systems for self-awareness/analysis, consisting of functions such as YG test module and Grouping Formation module.

1. Introduction

In the brave new world of Web Based Education (WBE), many educational systems have been proposed. Collaborative learning in WBE can be as effective as in face-to-face classroom activity, but it is not easy to design. In web-based collaborative learning environment, awareness is important to create efficient collaboration.

We believe that it is important to take into account human relations in collaborative learning environments - either face-to-face or web-based - where personality plays a central role. However, our view concerning the current situation of most Universities in Japan is that it has become difficult that to build human relations in face-to-face classroom, because students are not motivated to collaborate with their classmates. On the other hand, for the case of web-based classes, it is not easy to build human relations due to problems related to computer-mediated communication (CMC) .Matsushita et al 1995..

To overcome such problems, we propose the concept of personality information for awareness (PIA, for short), which represent information for self-awareness/analysis, self-disclosure, person awareness/analysis and person perception. We are designing a PIA-based system, called "PIAGETS (Personality Information for Awareness

BEST COPY AVAILABLE

applied to Group learning in web-based Education/ Training Support system)", which supported human relations building for collaborative learning in WBE.

In this paper, some fundamental studies for the design of PIAGETS are described. We first discuss the concepts of PIA and PIAGETS. Next, we report on the development of a sub-system called "YG test module" followed by sociometric investigation. Finally, we present an overview of the "Grouping Formation module" design.

2. PIAGETS for Human Relations Building

In this section, we first explain our motivation to focus on the human relations. Next, we propose the concept of PIA. Finally, the overview of our PIA-based system called "PIAGETS" is presented.

2.1. Attention to the human relations

The authors are in charge of an information system design class. By looking at the students, we note that their participation in the class is relatively poor. Their participation is more passive than active, like if they where watching TV, with no expression or reaction sometimes. The amount of discussion regarding lesson content with the classmate is poor. It seems like the human relations between learners is not deep enough.

We believe that such human relationships can be improved through discussions with classmates, thus the learning will be promoted. In our view, the functions necessary to support collaborative learning in WBE includes tools for cooperative work, support for knowledge awareness and understanding and functions for building human relationships.

In this paper, we focus on the function that supports the improvement of human relations.

2.2. Personality Information for Awareness (PIA)

According to [Ogata et al 1996], the collaboration process is lead from the following four processes: Co-presence, Awareness, Communication, Collaboration and Coordination. In collaborative learning environments, awareness is important to create efficient collaboration. We believe that it is important to take into account human relations in collaborative learning environments, where personality plays a central role. Thereupon, we propose the concept of PIA. Our hypothesis is that in order to build the human relationships, each learner pursues the communication activities shown in Figure 1.

† Person perception

Figure 1: Communication activities realized by each learner

BEST COPY AVAILABLE

Although the Figure 1 shows the student A as the focus of attention, the same activities are valid for student B.
The PIA represents information for:

- self-awareness/analysis: The process in which, the student A perform self-analysis in order to form the self-concept. By this, the student A discovers himself.
- self-disclosure: The process in which - from the results of self-awareness/analysis - the student A selects, some time decorates and shows to the public (student B in case of figure 1) only the selected/decorated information.
- person awareness/analysis: The process in which, the student B notice and analyze the personality information presented by others (student A in case of figure 1).
- person perception: The process in which – from the results of person awareness/analysis - the student B acknowledge whether or not to build interpersonal relationship with student A.

2.3. Overview of "PIAGETS"

We are designing a PIA based system, called "PIAGETS", which supported human relations building for collaborative learning in WBE.

PIAGETS is composed of the following functions, shown in Figure 2:

(1) Sub-systems for self-awareness/analysis,
(2) Sub-systems for self-disclosure
(3) Sub-systems for person awareness/analysis
(4) Sub-systems for person perception

Figure 2: PIAGETS functions

In this paper, we report with focus on (1) Sub-systems for self-awareness/analysis, consisting of functions such as YG test module and Grouping Formation module. We provide the details of YG test module and Grouping Formation module, in section 3 and section 4, respectively.

3. Basic investigation for face-to-face classes

We focus on face-to-face learning environments such as classrooms, where the learner is participating in the class by developing human relationships with the teacher and with the classmates. In order to make clear the structure of such human relationship from the personality viewpoint, we have conducted two investigations, described in the following subsections.

3.1. Development of YG personality test module, and personality test

In this research, we have focused on the YG personality test (Y for Yatabe, G for Guiford), which is a traditional method to examine the personality in Japan. First, in order to clarify the individual's character and their characteristics, the strength of 12 pre-defined personality trait are measured. Based on this measurement, the individuals are classified into 5 personality group types A, B, C, D or E. These 12 personality traits belong to one of 2 classes, where 6 belong to the "General emotionalism" class (D: Depression, C: Cyclic tendency, I: Inferiority, N: Nervousness, O: Objectivity, Co: Cooperativeness) and the remaining 6 to the "Extroversion/Introversion" class (Ag: Agreeableness/Aggressiveness, G: General activity, R: Rhythmic, T: Thinking extroversion, A: Ascendance, S: Social extroversion). Moreover, there are cases in which the individuals are judged to be of two or more of the A, B, C, D or E types, e.g. belonging to both type A and type C.

The original YG personality test has 120 questions. However, in order to reduce the time required to answer the questionnaire, we have used the trial YG personality test developed by Uehara, which consists of 36 questions.Uehara 1997.. In Uehara's trial test, the 5 personality types are named as follows: A as "average type", B as "black list type", C as "sedative type", D as "adaptive type" and E as "eccentric type".

We have developed a Web-based YG personality test, which we will refer as YG test module, for short. The module is based on CGI with Perl and a set of HTML Web pages. This YG test module can be used as a psychological testing to analyze self- personality objectively. (The output data is used in the Grouping Formation module.) An example of answer input screen and the result display screen for the YG test module are shown in figures 3 and 4, respectively. The user answers the questions given in the input screen by selecting one of the radio-buttons. When user finishes with the answers, the module calculates which of the personality group he belongs to and displays the results on the screen. A sample data of the personality that was obtained with the YG module is shown in Table 1.

3.2. Measuring the influence of student's " buddy" or " pal" on the personality structure

In order to measure the influence of the student's "buddy" on his personality structure, we have investigated using the YG test module the student's buddy concurrently with the execution of the YG personality test. Concretely - to clarify the student's buddy based on observations - we have observed several times the student's seat selection in the classroom.

First, based on the observations of the students in the classrooms, we have guessed the student's buddy as shown in Figure 5. For instance, the learners surrounded by lines in Fig. 5 were assumed to have some student's buddy. Then we have investigated the seating places in the classroom of the students, during 4 classes.

Figure 6: The students' seating position

The students' seating positions were plotted according to the axis shown in Figure 6, and the physical distance between students calculated using the formula 1. .Note : we have excluded from the study the students with more than 1 absence. From the position of the seats in the classroom, our assumption is that students with average physical distance of two or less (i.e. pair) show a student's buddy.

Table 2 summarizes the result of the mean distance and the YG test module for each pair. From the results of the Table 2 and Figure 5, we found correspondence in all pair of students, which prove the correctness of our assumptions. Thus, we have confirmed that buddies tend to seat close to each other.

3.3. Student's buddy are build between learners with different personality types

Basically, the data of the YG test module is judged to belong to one of the five personality types A to E. However, taking into account the cases in which a data can belong several types simultaneously, there are 31 possible combinations types (calculated based on the combinatorial formula 2). We can see from the results shown in Table 2 that the pairs are composed of learners belonging to different personality types. For instance, regarding the pair 2, the result of the YG test module shows that learner 12 is both C type and D type, while learner 6 is only type C. Thus, we can say from the results of the 4 pairs that in face-to-face classrooms, student's associates are build between learners with different personality types.

4. Grouping Formation Module based on Personality Information

We have developed a Web-based Grouping Formation module, based on CGI with Perl and a set of HTML Web pages. The Grouping Formation module uses the judgment result data from the YG test module. Based on the results of the judgment result data, the system propose the learner's grouping (pair) so that each group is composed from members with different personality types.

The group-formation process (pair) is done with 7-steps algorithm explained bellow:
Step 1: the learner's name is stored in the arrays, one array for each of the 31 type combinations.
Step 2: For each of the 31 arrays, the learners are re-ordered randomly.

Step 3: The number of learners is counted at each array, and the 31 arrays are ordered in descendent order, based on the total number of learners for each type, i.e. the array type with most learners first.

Step 4: In order to form the pairs, one learner is picked up sequentially, from the array with most learners and the second with most learners. Output the resulting pair.

Step 5: For step 4, if there are no more learners left on the array to form the pairs, then the next array with most number of learners is selected.

Step 6: Repeat the step 4 (and step 5 when necessary), to continue the pair formation process.

Step 7: When there is no two arrays of different types, then form the pairs randomly with learners from the same array.

5. Conclusion and Future Works

In this paper, we first discuss the concept of personality information for awareness, and a PIA-based system, called "PIAGETS", which supports human relations building for collaborative learning in WBE. Next, we report on the development of a sub-system called "YG test module" followed by sociometric investigation. Finally, we present an overview of the "Grouping Formation module" design.

Based on the data gathered from the YG test module, we worked to find out the influence of the student's buddy on the personality structure. We can see from the results that the pairs are composed of learners belonging to different personality types.

Future works include the evaluation of the effectiveness for our proposed PIAGETS, the investigation of the human relationship building process and the implementation of additional support functions for human relationship building.

Wearing Four Pairs of Shoes:
The Roles of E-Learning Facilitators

Ed Hootstein, Ph.D.
Intelligent Decision Systems, Inc.
edhoot@adelphia.net

The teacher-centered model that has dominated instruction for centuries is slowly giving way to a learner-centered conception with instructors in roles of facilitators, or "guides on the side." Active learning and collaboration increasingly characterize learning environments. E-learning is unable to promote learning on its own; its use does not preclude facilitators' responsibilities for structuring learning experiences. The effectiveness and success of e-learning programs depend on facilitators' roles in delivering and managing instruction. E-learning facilitators take on four roles to meet the necessary conditions of effectiveness, because they "wear four pairs of shoes," - instructors, social directors, managers, and technical assistants. The framework herein provides a means of describing tasks and responsibilities of e-learning facilitators.

Introduction

The emergence of e-learning comes during a time when education and training are undergoing important transformations. The teacher-centered model that has dominated instruction for centuries is slowly giving way to a learner-centered conception with instructors in roles of facilitators, or "guides on the side." (Bens, 2000; Hanna, 2000). Learning environments are increasingly characterized by active learning and collaboration (Mantayla, 2000; Rosenberg, 2001).

E-learning is unable to promote learning on its own; its use does not preclude facilitators' responsibilities for structuring learning experiences (Imel, 1998). The effectiveness and success of e-Learning programs are dependent on facilitators' roles in delivering and managing instruction.

The primary focus of this paper is the roles e-Learning facilitators must assume to be effective. The paper is organized in four major sections; facilitators "wear four pairs of shoes," - instructor, social director, program manager, and technical assistant (Collins & Berge, 1996).

A Framework for Defining Roles of E-Learning Facilitators

Instructor - Consultant, Guide, and Resource Provider

The role of facilitator as instructor is consistent with seminal adult learning research in which instructors guide self-directed learning in problem-centered environments (Cross, 1998; Knowles, Holton, & Swanson, 1998; Wlodkowski, 1993). Facilitators are resources for learning rather than instructors who have all the answers (Brookfield, 1986). They employ some of the same best practices as traditional classroom instructors (Merriam & Calfarella, 1998), however the roles assumed and skills used differentiate the two approaches.

Facilitators provide their own unique insights as they guide learners to acquire knowledge and develop skills. Their primary instructional tasks are a) providing information to help learners complete assignments, b) suggesting ideas or strategies, and c) helping learners to connect content with prior knowledge (Collins & Berge, 1996).

A discussion of some best practices and their implications for E-Learning is presented below.

Fostering Learner-Centeredness

Educators in the field of adult learning (e.g., Brookfield, 1986; Merriam & Caffarella, 1998) support the premise that facilitators humanize self-directed learning by focusing on learners rather than technology (Willis, 1993). The essential quality of learner-centeredness is most relevant when learners are personally challenged with a problem to solve, a project to complete, or a dilemma to resolve (Abbey, 2000; Schreiber & Berge, 2000).

Facilitators and learners often participate together as partners in learning activities (Driscoll, 1998; Merriam & Calfarella, 1998). Specifically, facilitators guide learners to play a part in determining course direction by discovering content on their own, carrying out assignments and projects (Kearsley, 2000), and creating learning opportunities to meet their own needs (Khan, 1997).

Implications for E-Learning

The variety of interactive tools and resources on the World Wide Web highlight the importance of selecting instructional methods (e.g., forums, case study analyses). Facilitators manage the distribution of learner-selected activities and scaffold them with comments and support to guide and support learner achievement (Khan, 1997).

In virtual asynchronous environments, learners are often expected to participate in establishing an agenda, defining objectives, and assessing outcomes. In virtual synchronous environments, learners may share responsibility for programs when facilitators take roles as mutual learners.

Structuring Problem-Based Learning and Authentic Work

Facilitators structure realistic problem-based experiences to make content more personally meaningful for learners (Woolfolk, 1998). Knowledge is adapted to the settings, purposes, and tasks to which it is applied (Greeno, Collins, & Resnick, cited in Berliner & Calfee, 1996; Lave & Wenger, 1991).

Facilitators tend to change their style of teaching from didactic to project-based approaches in which learners ask questions, perform investigations, and act on their findings. They also use strategies such as small-group discussions, simulations, case studies, and collaborative activities to engage learners in problem solving (Khan, 1997). They ask questions and closely monitor learners' efforts and are available for assistance (Hanna, 2000).

Implications for E-Learning

Problem-based learning is compatible with e-learning because both environments can be highly authentic in nature and provide access to resources and expertise. Facilitators help learners use the conferencing capabilities of the World Wide Web to provide them with access to expert thinking and modeling. In real-life settings, experts and those who are more experienced help learners solve problems. The resources of the web also can be utilized in an authentic context for solving problems using the strategy of cognitive apprenticeship. Experts and learning guides may be available through mentoring, tutoring, learner work groups, etc. (Khan, 1997).

When learners practice what experts in their discipline do each day, the real nature of technology to change the curriculum occurs. Facilitators are free to use strategies that allow learners to edit, revise, and try again, thus taking an authentic approach to problem solving (Shreiber & Berge, 2000). In this way, technology may change the curriculum without changing the content.

The uses of email, e-conferencing, web databases, groupware, and audio/videoconferencing significantly increase the extent and ease of interaction amongst all participants. The vast array of software tools available for analysis, design, planning, problem solving, and making presentations enable learners to perform sophisticated and complex tasks. Technology provides a milieu that fosters the kind of creativity and communication needed to solve problems in creative ways.

Providing Informative Feedback

Some educators (e.g., Hiltz, 1995) believe that the most important facilitator behavior is timely and personal response to questions and contributions of learners. Facilitators provide informative timely feedback with concise brief statements. They a) offer learners guidance about how they might improve their performance, b) communicate what learners have and have not demonstrated, and c) provide learners with specific detailed information about strengths and weaknesses of their performance.

Both what facilitators say and how they say it has an impact on learners. In fact, the ways facilitators respond may have greater influence on learner behavior than questions asked. In addition, learners' perceptions of their progress may be more important than positive facilitator evaluation of their work (Brookfield, 1986).

Although praise appears to be an encouraging response, making judgments is associated with bringing conformity. If praise is given, facilitators must communicate why performance is positive. For example, "your speech is clear and concise" provides more constructive feedback than "Good job, I like the way you speak" (Brophy, 1998). Facilitators may offer praise or encouragement, however a preferred alternative is to encourage learners to evaluate their own responses.

Implications for E-Learning

Feedback is even more critical in e-Learning than traditional classrooms because learners may feel isolated and detached due to lack of environmental and nonverbal signals. (Kearsley, 2000; Khan, 1997; Willis, 1993).

Constructive and extensive feedback to individuals usually takes the form of email messages about assignments or comments on assignments. Facilitators may also summarize and/or synthesize individual responses given on a topic or activity by posting messages in a discussion forum or conference.

The element of timely feedback is especially important (Kearsley, 2000; Khan, 1997; Paloff & Pratt, 1999). Facilitators should establish a standard such as a forty-eight hour turnaround time.

Learners should provide feedback to each other too; facilitators must establish peer feedback as an expectation in delineated guidelines posted at the beginning of a course. Guidelines can be discussed and negotiated by all learners (Paloff & Pratt, 1999).

Social Director - Creator of Collaborative Environments

Fostering Collaborative Learning

The process of facilitation itself is collaborative. Facilitators and learners are involved in a cooperative undertaking in that leadership and facilitative roles are assumed by different group members to initiate and guide learning efforts.

Underlying collaborative learning is the belief that learners achieve best in social interactions based on consensus building and cooperation. (Brookfield, 1986).

As they promote interpersonal relationships and help learners work together, facilitators guide a developing sense of community within and between small groups. Perhaps the most meaningful facilitation in this collaborative structure is modeling interaction techniques and assuming the role of a group member who contributes to learning (Paloff & Pratt, 1999).

Facilitators stimulate learner participation and interaction by using small group discussions, collaborative projects, case studies, dyadic learning partnership exchanges, and one-on-one exchanges (Berge, 1995). In addition, they monitor and participate in discussion forums or conferences to identify misconceptions or guide more fruitful directions.

Effective facilitators keep discussions focused on the topic, bring out multiple perspectives, and summarize and synthesize main points (Berge, 1996; Kearsley, 2000; Salomon, 2000). They use questions and probes to help learners connect around shared problems, interests, and experiences (Collins & Berge, 1996; Paulsen, 1995).

Implications for E-Learning

Experts in the field of e-learning (e.g., Collins & Berge, 1996; Kearsley, 2000) contend the most important facilitation skills involve encouraging and ensuring a high degree of interactivity and participation. Facilitators support the learning process through the use of collaborative assignments and active discussions.

Interactions among learners may be almost as important as content-oriented goals. Therefore, facilitators begin a course by posting introductions and encouraging learners to seek areas of common interest as they meet in distinctive gathering places, such as chat rooms (Paloff & Pratt, 1999).

Facilitators encourage interaction among learners, facilitators, and subject-matter experts via the Internet using email, list serves, news groups, multi-user discussions (MUDs), forums, Internet Relay Chat, (IRC) and conferencing (Berge, 1996; Driscoll, 1998; Kearsley, 2000; Paulsen, 1995). Kearsley (2000) suggests the use of tangibles such as discussion areas, learner directories modified by learners, and newsletters relevant to particular fields of study.

Facilitators can not be in control of everything learned, given the limitations of time and access to the learner population. Therefore, they guide learners in working together to become more skilled in areas such as scheduling, project management, time management, consensus building, and leadership.

Program Manager - Director of the Agenda

Facilitators as managers are responsible for organizational, procedural, and administrative duties. A consistent theme in the literature is the facilitators' use of organizers to provide an overview of a course. In addition, they show strong leadership, managing interactions proactively by defining expected behaviors of learners through guidelines, protocols, and netiquette (Berge, 1995).

Facilitators develop study guides for courses to help ease learners' anxiety and address both the content and any common technical concerns. Study guides provide introductory information, describe learning activities and resources materials, and provide additional information about course components or procedures (Berge, 1995).

Facilitators are available to help learners manage their time and avoid information overload (Salmon, 2000). Many learners may not be accustomed to increased independence and the vast array of available information.

Technical Assistant - Model of Proficiency

Facilitators as technical assistants help learners become comfortable with systems and software. Assistance also includes preparing learners to resolve any technical difficulties that may occur. The ultimate technical goal for facilitators is to make the technology transparent. When this occurs, learners may concentrate on the academic task at hand (Berge, 1995). The more familiar facilitators are with the technology, the more they can focus on learners rather than technology (Madden, 1998).

Effective facilitators feel comfortable using media and communication tools. Ideally, they can use a variety of media (text, graphics, audio, video) to present material. Such variety may accommodate individual learning styles and provide approaches for both visual and auditory learners (Jones et al.). As an example, "Gen-Xers" typically prefer fast-paced presentations with visual images and frequent feedback.

Summary

This paper has described tasks and responsibilities of e-Learning facilitators as they take on four distinct roles - instructor, social director, program manager, and technical assistant. The following responsibilities represent a considerable aspect of an E-learning facilitator's efforts:

- Address needs of adult learners by guiding self-directed, realistic, problem-based learning experiences.
- Structure learning opportunities in which learners make their own meanings by discovering content on their own.
- Encourage high degrees of participation and interactivity.
- Offer prompt, informative feedback.
- Provide strong leadership.
- Help learners feel comfortable with technology.

Steps should be taken to develop standards for development and implementation of quality e-Learning programs. It is prudent to establish standards for facilitators' responsibilities. Framing their roles generically herein is a step toward helping them be more cognizant of their efforts.

Development of An Internet Collaborative Learning Behavior Scale – Preliminary Results

Ti Hsu
Department of Business Administration
Tamkang University
Taipei, Taiwan, R.O.C.
th4657@yahoo.com

Hsiu Fei Wang
Da Yeh University and New York University

Abstract: It is well known that math phobia is a common problem among young school kids. It becomes a challenge to educational practitioners and academic researchers to figure out ways to overcome the problems. Collaborative team learning has been proposed as one of the alternatives. The present study was part of a large and an on-going research project designed to help students learn math in a collaborative fashion using a Web-based intelligent system in a virtual reality environment and then to study their learning behaviors. The purpose of this part was to develop an instrument to measure the learning behavior of Taiwan's 8^{th} graders in their learning of the "Pythagorean Theorem." A principal component analysis with the Oblimin procedure was utilized to analyze the 44-item internet collaborative learning behavior scale (ICLBS). The preliminary results revealed that a model with five-factor deriving from 39 item was the best model.

Introduction

Math has always been a very difficult subject to many elementary and/or junior high school students. For years, educational practitioners and academic researchers have continuously worked hard to generate new ideas or alternatives hoping to help alleviate the pressure for students to learn math.

Collaborative learning has been offered as one such alternative to the traditional way of teaching and/or learning. Unlike individualized learning, collaborative learning tends to place heavy emphasis on cooperative learning and the development of certain important skills, such as thinking, interpersonal, and problem solving, etc.

Plowman's (1988) cooperative team learning theory claimed that students could be encouraged to learn on their own through discovering and experiencing themselves, which in turn would also motivate them to learn more willingly. This would be an ideal way of learning and might be deemed as the most effective way of learning. This is why researchers believed that cooperative team learning not only tended to offer better learning than individual learning, but also helped students enhance their self-esteem (Salvin, 1990; Sharan & Shacher, 1988). A better and effective learning provided through the "cooperative team learning" was further supported by the findings of two separate research (Johnson & Johnson,1989; Cooper, et al 1990). Another study undertaken by Webb (1991) revealed that students could obtain better grades if they would participate actively in the team discussion, or if they could answer questions that other members might have, or if they could explain the key points or the highlights of the subject under study. Still, another research (King, 1990) claimed that there was a significantly positive correlation between cooperative team learning and the learning performance.

In a cooperative team learning environment, there are a number of different roles that students need play. They may include the sharing of the leadership, information receiving and providing, coordinating, conflict handling, etc. Team members with different roles will definitely affect the interactive behavior among themselves and the final outcome of the learning as well. Generally speaking, they are five major categories of interactive behavior (Adams, Carlson, & Hamm, 1990, p.12), including 1) information or idea seeking; 2) information or idea providing; 3) information or idea clarifying or explaining; 4) information or idea inductiveness; and 5) process managing.

BEST COPY AVAILABLE

Moreover, as part of the idea generation process, team members may display certain behavior that is related to the process managing (Adams, Carlton, & Hamm, 1990, pp. 13-14). Those processing managing behaviors are: 1) compromising; 2) encouraging; 3) gatekeeping; 4) tension releasing; and 5) sharing of feelings and emotions.

The present research was part of a large research project, which was designed to help students learn math in a collaborative fashion via a Web-based intelligent system in a virtual reality environment called Waltz and then to examine their learning behavior. The purpose of this task was to develop an instrument in order to measure the learning behavior of Taiwan's 8th graders in their learning of the "Pythagorean Theorem." Like this task, the Waltz and an intelligent agent system to learn the concept of "Pythagorean Theorem" were both developed as part of the large on-going research project funded by the National Science Council in Taiwan.

Importance of the Study

In education, it is well known that the most effective learning method is to cultivate students' thinking ability, which is what cooperative or collaborative team learning is all about. In addition to its emphasis on thinking, it also encourages students to learn new materials or skills and to solve problems collectively through interactions. Due to the fact that a lot of junior high school students have math phobia, it was the intent of the study to examine how effective cooperative learning might be able to help overcome or reduce the fear. This was one of the main reasons why this study was designed in the first place. Past studies on collaborative team learning tended to concentrate on the effects of "heterogeneity," such as race, gender, culture, individual ability, etc. among members of a team. Not much attention has been paid to the "homogeneity," which is what the present study was designed to do.

Moreover, studies of cooperative team learning in the past placed heavy emphasis on the comparison of individual learning and group learning in terms of their effectiveness, their motivation, cultivation of self-esteem, etc. Few studies have been conducted to evaluate the group learning process, the interaction among group members, and the group dynamics and their potential impacts. This is especially rare in Taiwan.

Methods

Sampling

The sample used in the project consisted of 134 subjects. They were all eighth graders drawn from two junior high schools in Taiwan. Both schools are located in the central part of the island. One was from an urban area with 65 students and the other from a rural area with 69 students. The sex distribution of the participants was about even in both schools.

Instrument

Since the principal purpose of the present study was to develop a reliable instrument to measure the collaborative team learning behavior of Taiwan's 8th graders in their learning of the "Pythagorean Theorem" in the internet. The scale to be developed and tested was called the internet collaborative learning behavior scale, or ICLBS in short. The scale was initially composed of 44 items. They were compiled after an extensive examination of past studies on the topic and a careful review of a number of related questionnaires. Each item was scored on a seven-point Likert scale with one being the least agreeable and seven being the most agreeable.

Procedure

Experiments were carried out in the computer labs of the two respective junior high schools mentioned above in August 2001. Prior to the experiments, the Waltz system, which was a Web-based intelligent system in a virtual reality environment, was set up in the respective labs. At the outset of each experiment, participants were explained of the nature of the project and were administered a pre-test on materials, that were related to the "Pythagorean Theorem", but had not been taught by their teachers. They were then assigned randomly to small collaborative learning teams with three or four members per team. They were mixed regardless of their ability levels, as judged by their GPAs, gender, computer efficacy, and individual learning style.

At the beginning of each experimental session, members of each collaborative learning team were assigned seats far apart from each other so that no two members would be able to see each other and/or to communicate with each other verbally. Each student was also assigned a computer for his/her sole use. The total duration of the experiment lasted 45 minutes (it should be noted that the students had been classmates for almost two years, thus reducing the need to go through the four group development stages). The first 15 minutes were devoted for the participants to get familiar with the Waltz system and to communicate to each other on any topics they cared to via the internet. In essence, this was the warm-up period for the subjects to get to know the system. The second phase of the experiment was a 30-minute session, which required subjects to learn and solve collaboratively as a team a new algebra problem related to the "Pythagorean Theorem," which was presented in a multimedia form in a virtual reality environment.

At the end of the 30 minutes, they were administered a post-test on the subject again to check how much they had just learned collaboratively as a team. In addition, the 44-item scale was also administered to each of the team members along with some other scales that were not part of the present study. A debriefing was followed immediately thereafter.

Results

Descriptive Statistics

The descriptive statistics for the 44-item internet collaborative learning behavior scale (ICLBS) are presented in Table 1 below.

	Mean	S. D.	Alpha if item Deleted
1. In my team, there existed a positive interdependent relationship (cooperation) among team members during the interactions.	5.52	1.39	0.9016
2. In my team, there existed a negative interdependent relationship (competition) among team members during the interactions*	3.79	1.81	0.9051
3. In my team, there didn't exist any interdependent relationships among team members, resulting in very limited interactions*	4.17	1.74	0.9040
4. In my team, everyone committed oneself to the process of the collaborative team learning	5.04	1.46	0.9034
5. In my team, everyone knew one's own role clearly at any given time	5.06	1.36	0.9020
6. In my team, everyone knew one's responsibility	5.10	1.44	0.9008
7. In my team, everyone did one's duty satisfactorily	5.20	1.42	0.9006
8. In my team, I learned a lot from my teammates that I wouldn't otherwise learn them by myself	4.87	1.57	0.9030
9. In my team, I learned a lot of new knowledge	5.25	1.69	0.9014
10. In my team, I learned a lot of new ways of thinking	5.00	1.72	0.9010
11. In my team, I learned a lot of new study skills	5.12	1.43	0.9001
12. In my team, I learned how to interact actively with others	5.03	1.41	0.8989
13. In my team, I learned how to analyze the problems we faced	5.00	1.72	0.9005
14. In my team, I realized the force of the group synergy	5.06	1.34	0.9000
15. I think the computer contents were very attractive	5.15	1.51	0.9002
16. I think the computer contents were abundant	5.34	1.41	0.9020
17. I think the computer contents were pretty vivid	5.19	1.59	0.9015
18. I was very satisfied with the computerized study environment	5.18	1.34	0.9022
19. The computerized study environment gave me an impulse and made me want to learn more	5.00	1.41	0.9011
20. The computerized study environment actually made me learn more than I had expected to	5.23	1.51	0.9005
21. I think the interactions of our team helped very little on the topics that we were supposed to learn*	3.58	1.70	0.9056
22. I think my teammates rarely challenged each other during the collaborative learning process*	4.16	1.51	0.9034

BEST COPY AVAILABLE

23. I think most of my teammates lacked any innovative ideas during the collaborative learning process*	3.87	1.55	0.9017
24. I think most of my teammates lacked any active thinking that might help generate new ideas*	4.16	1.52	0.9018
25. I think most of my teammates rarely expressed their opinions during the collaborative learning process*	4.46	1.72	0.9016
26. I think the team interactions in my team were dominated by only a few most of the time	3.98	1.68	0.9018
27. I think my teammates often had no ideas of how to actively participate in the interactions*	3.91	1.66	0.9015
28. I think my teammates often had no ideas of how to analyze the problems we faced*	3.83	1.55	0.9041
29. I think my teammates often had no ideas of what they were doing during the collaborative learning process*	3.83	1.56	0.9052
30. I think my teammates often had no ideas of how to express their opinions during the collaborative learning process*	4.26	1.61	0.9049
31. I think my team did not have any member with a high GPA*	3.63	1.82	0.9054
32. I think my team did not have any member with a high IQ*	3.56	1.69	0.9048
33. In my team, I realized the practical value of team learning	4.80	1.55	0.9012
34. I think collaborative team studying was a good way of learning.	4.97	1.62	0.9009
35. I realized that I needed to improve on my interpersonal skills during the collaborative learning process*	4.68	1.50	0.9017
36. I had no problems expressing my opinions openly in my team.	4.56	1.53	0.9015
37. I had no problems expressing my difficulties openly in my team	4.41	1.61	0.9005
38. I think we all needed to improve our interpersonal skills in my team*	4.44	1.51	0.8999
39. I think my teammates made me realize the importance of appreciating the thoughts and the problems of others more.	4.73	1.46	0.8985
40. I think my teammates made me realize the importance of caring others more.	4.89	1.60	0.8989
41. I think we needed to clarify more of the problems we faced during the collaborative learning process*	4.73	1.54	0.9008
42. I think my teammates lacked a basic trust of each other*	3.95	1.69	0.9008
43. I think my team had a good control of the time during the collaborative learning process.	4.71	1.52	0.8989
44. I think my team processed excellent decision-making abilities	4.78	1.51	0.9004

Alpha = 0.9038

Table 1 Descriptive Statistics and Reliability Analysis

Reliability Analysis

Cronbach alpha correlation coefficients were computed for each of the 44-item scale. Table 1 above presents the results of the reliability analysis as well as the means and the standard deviations. As can be seen, the Cronbach alpha coefficients were 0.9038 for the total scale and at least 0.8985 to as high as 0.9052 for the individual items. The results indicated that the 44-item internet collaborative learning behavior scale (ICLBS) and the individual item had high internal consistency. As such, all 44 items were retained for further analyses.

Factor Analysis

Once the internal consistency analysis was completed, a factor analysis was carried out. A principal component analysis of the 44-item was conducted using Oblimin with Kaiser Normalization procedure of the Statistical Package for the Social Sciences. The procedure extracted 11 factors with eigenvalues greater than 1.0. The largest of the 11 factors accounted for 22.06% of the pre-rotation variance whereas the smallest factor accounted for 2.36% of the variance, for a total variance of 70.03%.

BEST COPY AVAILABLE

Using Gorsuch's (1983) recommendation of considering both the Kaiser-Guttman criterion (Kaiser, 1970) of retaining factors with eigenvalues greater than 1.0, it seemed that the 11-factor model was inappropriate since three of the 11 factors only accounted for between 2% and 3% each. It was decided to

Table 2: Rotated Component Matrix

review the 11-factor model further using the scree test as suggested by Cattell (1966). A quick visual check of the scree plot revealed two break points in the plotted line of eigenvalues after 5 factors, which accounted accumulatively for 50.53%, and 7 factors, accounted collectively for 58.27%.

The rotated component matrix was utilized for the interpretation of the final factors to be extracted. Since the sample size was 134, an item in order to be retained had to have a component coefficient of 0.50 or greater to be statistically significant, according to Hair, Andersen, Tatham, and Black (1998, p.112). Another word, items with component coefficients of less than 0.50 should be deleted from the instrument. The results of the rotated component matrix tended to indicate that the five-factor model was more appropriate than the seven-factor model. Table 2 shows the results of the factor analysis with the five-factor model.

Discussion and Summary

The results showed in Table 2 above indicated that the scale was basically a five-factor model. Those five factors were respectively named computer usage, role behavior, openness, passiveness, and incapacity..

Computer Usage Factor

The inclusion of the computer usage factor with seven items in the five-factor model, is understandable. This is because computers are rapidly becoming part of the educational process from K to G12 in Taiwan. A major difference between collaborative learning with and without computers is that end users have technological tools that can allow for dynamic exploration via time, space, and ideas in an interactive method.

The successful use of computers means involving both teachers and students in the learning process in a completely different way. Web-based collaborative team learning can help sharpen students' ability to think critically and to develop independent judgments. It is also intended to teach cooperative social skills, individual accountability and group information processing within a group environment.

With the advancement of complicated computer software nowadays, it is no wonder that the Web can be and has been employed easily to collaborate learning on how to undertake a task or project so long as it also offers abundantly attractive multimedia contents. The emergence of this factor certainly attests to that.

"When the excitement of discovery is assisted by peers and the imaginative spirit of inquiry, learning is at its best (Hamm & Adams, 1992, p.87)." It is not surprising to note that "the computer is a natural learning vehicle for cooperative group work (Mandell & Mandell, 1989)."

Role Behavior Factor

As any group behavior researchers can readily attest that there are a variety of roles that team members need to play. They may include, but are not limited to, sharing of the leadership, information receiving and providing, coordinating, conflict handling, etc. What role one member may play within a group depends, to a large extent, on one's perceived concept of identify. The importance of the role of identity was not recognized until the social identity theory was introduced (Tajfel and Turner,1979) . In essence, there are four properties of identity, including identity as rational, situational, interactive, and affective (Hertz-Lazarowitz & Miller, 1992, p.204). The identification of the second factor, role behavior factor, which contained six items, certainly verifies the point.

Openness Factor

How successful a team functions depends, to a large extent, on how open the team and its members are. This is because openness has a lot to do with imagination, artistically sensitiveness, and intellectualism. It also encourages and opens up new ways of communication, stimulates more creativity and innovations within a group. This is not to mention that openness may also help build up the cohesiveness in a group, which is the degree to which group members are attracted to each other and are more likely to be motivated to stay in the group so that they get a stronger feeling of "I belong." Needless to say, there is a potentially positive correlation between the group cohesiveness and the group productivity.

The 13 items that were identified as part of this factor included such items as "expressing my opinion openly (v.36)," "expressing my difficulties openly (v.37)," "made me realize the importance of appreciating the thoughts and the problems of others more (v.39)." This is perhaps why the "force of the group synergy (v.14)" was also recognized here as well.

Most of the 13 items are essential to the building of "trust," which is a crucial issue and perhaps the most difficult one to deal with when it comes to the effectiveness of a group or an organization (Gammetta, 1988; Lewis & Weigert, 1985; Mayer, Davis &Schoorman, 1995). Numerous research (Chidambaram, 1996; Deutch, 1958; Handy, 1995; Leidner & Jarvenpaa, 1995; Meyerson, Weick & Kramer, 1996) has uncovered this. It is not surprising to hear that "Although trust usually is thought of in the context of a long-term relationship, when people join teams for a short period of time, building and maintaining trust is more difficult and, therefore, more important (Durate and Snyder,1999, (p.83)."

Passiveness Factor

It is not surprising to see that "passiveness" showed up in the factor analysis as one of the key factors, which covered 5 items. This may be attributed to two reasons. First, collaborative team learning is a very new way of learning in Taiwan's culture. There has been a tendency to over-emphasize the individual accomplishment at the expense of the group learning. As a result, students often find themselves in a state of competing each other than in a state of working together cooperatively. Second, whenever students are assigned a group project, they are always given the opportunity to form their own teams. As such, groups are often composed of close friends, who are often time socialized together outside the classroom as well. In groups like those, projects are often time carried out not by the entire team, but by a so-called the "core group.". In other words, "free rider" is a common problem. The emergence of the "passiveness" factor is therefore understandable and not surprising.

Incapacity Factor

This factor had eight items and is a very interesting one. It is interesting because it showed all the negative aspects of the teamwork. The indifference of its members might be attributed to a fact that most, if not all, of its members were followers waiting for someone to stand up to take the leadership role. Yet, no one did emerge as either the team leader or the opinion leader because of low IQ (v. 32) and/or low GPA (v. 31). As a result, every one seemed to have lost in the collaborative team learning process. This was why the group as a whole did not know how to participate (v. 27), how to analyze (v. 28), what to do (v. 29), and how to express their opinions (v. 30). Basically, the whole learning process was a terrible mess for the group. This situation is not unusual for a self-directed or self-managing team, which is common with today's virtual teams. Therefore, it is crucial to have a balanced team with members equipped with different background, experiences and functions.

Conclusion

The present study showed that it is possible to construct a questionnaire in order to assess the interactive learning behavior of 8th grade students in a collaborative team learning environment relying on multimedia and virtual reality technologies. The level of homogeneity of the scale as assessed by Cronbach's alpha (0.9038) was very high. The final form of the scale was composed of five factors with 39 items in total. While this is true, two things need be emphasized here nonetheless. First, the findings of the study are only preliminary and should be treated as such. Second, since the subjects of the study were 8th grade students in Taiwan, the conclusion should not be generalized and the scale may not be applicable universally.

Abstract: The development of authoring tools for intelligent systems is an important step for creating, maintaining, and structuring content in a quick and easy manner. It has the benefit of allowing for a rapid change to new domains or topics for tutoring. The development of such tools requires functional control, access protection, easy of learning, and ease of use. In this paper, we introduce the authoring tool we created for the Human Use Regulatory Affairs Advisor (HURAA). HURAA, is a web-based help facility that provides training on the ethical use of human subjects in research, in addition to serving as an information retrieval system on ethical research policies. EBOOK.EXE is a general purpose database organization tool with special features that can be used for organizing curriculum scripts for intelligent tutoring systems.

Introduction

HURAA is one of several projects currently conducted in the Institute for Intelligent Systems (IIS) in the University of Memphis. HURAA is designed for higher level military personnel to evaluate the ethical conduct of research using humans (Graesser, Hu, & Person, 2001). The content of HURAA is derived from Federal agency documents and regulations, particularly the National Institutes of Health (NIH, 45 CFR 46), the Department of Defense (32 CFR 219; DoD Directive 3216.2), and other particular policies from branches of the US military. The users of the HURA Advisor are high-ranking military officials who must approve research protocols involving human subjects in studies sponsored by the Department of Defense (DoD). These users focus on fundamental ethical issues, but not the detailed procedures and paper work associated with gaining approval from Institutional Review Boards. The purpose of HURAA is to allow users from the DoD to obtain important information, regulations, and guidelines in a short amount of time (less than 30 minutes) using the HURA Advisor.

Similar to most of web-based training systems, HURAA contains two major modules: Content and a Learning Management System (LMS). Content is the organized knowledge structure of the information to be delivered to the user. LMS, on the other hand, are a collection of server applications that manage the contents, monitor user-sever interactions and deliver appropriate information to the user. We will first briefly describe the contents of HURAA, and then we will introduce some key features of EBOOK.EXE. The LMS of HURAA has been described in previous papers and thus will not be discussed here (see Graesser, Hu, & Person, 2001).

HURAA

HURAA provides several learning trajectories to users. Within these learning trajectories, two types of learning activities are encouraged: (1) linear order browsing, namely, following scripts in a fixed order (e.g., Historical Overview and Lessons, as illustrated later) and (2) free style browsing of content with the aid of a semantic searching algorithm (e.g., Latent Semantic Analysis or LSA, see Landauer, Foltz, & Laham, 1998). The searching algorithm is a glorified search engine that uses semantic information to help the user obtain desired information from the database. Using these types of learning, HURAA is used to aid users in obtain important information, regulations, and guidelines they need in a short amount of time (less than 30 minutes) to make decisions on ethical human subject research. To make this possible, HURAA tries to help users make connections between major ethical issues and specific cases. That is, the users attempt to identify what ethical issues are problematic for any particular experiment (case). A theoretical case-issue matrix specifies what experts view as the problematic issues for particular cases. Additionally, HURAA houses a context sensitive FAQ function (Point & Query, Graesser, Langston, & Baggett, 1993) so users can ask questions at any point while they are using the system. HURAA makes available other information facilities that are convenient. For example, all glossary items are automatically highlighted throughout the system, so user can obtain definitions of any of the key items without switching to another interface or page.

EBOOK.EXE

EBOOK.EXE is a general-purpose database organization utility. It is written in Pascal and compiled using Delphi 6.0. System equipment and software needed to operate EBOOK is any modern version of Microsoft Windows™ (95/98/2000/XP). Another software requirement is an ADO connection to Microsoft SQL server database (however, it can be any ODBC compliant database locally, if there is no network connection). EBOOK.EXE organizes several database tables (data table for contents, data table Point and Query, Data table for LSA, data table for glossary, etc) with predefined field definitions. The user-interface of EBOOK.EXE is typical of any Windows™ desktop application (see Figure 1).

Organizing HURAA in EBOOK.EXE

BEST COPY AVAILABLE

HURAA's contents are organized to emulate either the linear structure of an ordinary book (such as going through the Lessons on the system) or to allow the perusal of a hierarchical outline of knowledge on the topic (as is seen above in the Exploring Issues module). To accomplish this HURAA, uses a relational database with each entry containing several types information. (1) Visible elements, which include: a. text & multimedia, b. associated Point-and-Query items. c. talking head events (what animation will the talking head play, and what tip the talking head will give) and (2) logical elements, which include: a. type of entry (normal/display entry, question entry, multiple choice entry, feedback entry, etc); b. order information (such as which entry will be the default next to display).

According to Murray (1999), HURAA falls in to the new category of intelligent systems called Intelligent and Adaptive Hypermedia. This category is on the cutting edge of web-based media and as such takes strategies from both intelligent tutoring and hypermedia. Authoring tools developed for this category of systems are more difficult to create since they must adapt directly to the methodology used in building the system. Additionally, these types of systems make use of databases, control links, execute tutoring strategies, and adapt to the student, adding to the difficulty (see Murray 1999).

In the past desktop authoring tools have been developed that focus on insulating the user from the underlying architecture and programming of an intelligent system (Jordan, Rose, & VanLehn 2001). This left the user with little control of the structure of the learning, and limited the variety of delivery within these systems to predefined constraints. With EBOOK.EXE we wanted to abandon this type of approach and dramatically increase the control of the knowledge engineer. An advantage of such a desktop authoring tool is that it can offer more total control of the system because it takes advantages of windows user interface (such as drag and drop and variety of functional components). EBOOK.EXE is designed to use ADO and data-aware component in Delphi, so it transmits its data to the centralized server to make updates and changes simultaneously.

A description of useful features and limitations in EBOOK.EXE follows where we note our observations in authoring HURAA contents using the EBOOF.EXE authoring environment.

Graphic Interface

The most important advantage of a desktop application is the capability of using the Microsoft Windows™ graphic interface with which most users are familiar. Building upon this interface, EBOOK.EXE exploits several visual components that make it possible to display the structure of the content organization in a simple and easy to comprehend manner. A graphic tree overview of the contents and its structure allows the user to navigate through the entire course within the interface, as shown in Figure 1.

We used the tree view to display the organized knowledge, allowing authors to concentrate on the contents, and not the html code. In fact, this authoring tool does not require any knowledge of HTML coding. The database organizes the information, and the server application produces the final web pages from the database (using HTML and XML) that reflects hierarchical structure of the content. For example, the hierarchical tree structure corresponds identically to the organization of the material into Modules, Issues, Topics, and Points as is seen in Figure 2.

To be ethical, research must be reviewed by an independent body, typically an Institutional Review Board (IRB). The federal regulations on IRB review apply to "all research involving human subjects conducted, supported, or otherwise subject to federal regulation by a federal department or agency" that has adopted the human subjects regulations.

- Department of Defense review

Figure 2: HURAA interface.

The authoring tool allows the user to view/edit every aspect of each entry. If a special link needs to be displayed on a specific page, then it can be incorporated into the content with ease. If a deviation from the default display HTML is needed on a certain page of content, it can be explicitly marked up for that page only.

There are several other authoring tools for different intelligent systems. EBOOK.EXE tries to maximize the advantages of a windowing system, so it helps the user to concentrate on the content, not the format of the final deliverable web pages.

Different Levels of Editing

It has been pointed out that developing authoring tools for Intelligent and Adaptive Hypermedia (Murray, 1999) is difficult due to the complexity of the relations among the entries. For example, there are default learning trajectories that user needs to follow. There is also conditional branching that needs to be stored in the database. For every entry, there is other information associated, such as Point-and-Query (most frequently asked question for that entry only), search index (LSA vector, or keywords, etc), cross-links to entries in other data tables (such as case-issue matrix). It can certainly be overwhelming for inexperienced users, since they are only understandable to sophisticated trained users. EBOOK.EXE tries to allow for editing at different levels, so different users only concentrate on material that is relevant to certain editing level proficiencies. For example, content experts can concentrate on the logical relations of the content organization. Cognitive psychologists can make modifications on the interface (such as the talking-head scripts for the guiding of navigation), and computational linguistics experts can work on the

BEST COPY AVAILABLE

LSA or other search indexes. It is in this manner that the complexity of the HURAA system can be distributed and comprehendible to users at various levels.

Import and Export

There are built-in utilities in EBOOK.EXE for importing and exporting the contents of the database into another format (such as another database, html, or XML). The content of HURAA is organized entirely in a database. As a result, it is relatively straightforward to convert the authored contents to other formats. EBOOK.EXE allows authors to export the entire data script to HTML. Most importantly, EBOOK.EXE has a built in conversion utility that exports the contents to XML metadata that is conformant with the Shareable Content Object Reference Model (SCORM). We use XSL to process the XML form of the content database. Currently, XSL for SCORM 1.2 is built-in. For future versions of SCORM, only minor modifications of the XSL files are need for the future versions of SCORM. Modification of the XSL files can be done using EBOOK.EXE or commercial packages such as XMLSpy (see http://www.xmlspy.com/).

Limitations

Most of the features on EBOOK.EXE are still at a functional level, and are not yet user-friendly. For example, EBOOK.EXE uses ADO to remotely connect to the data server on the network (or internet). This is a nontrivial step for users without knowledge of Windows™ database. In addition, the editing of talking-head event requires a special type of mark-up for Microsoft Agent™. And the converting utility to XML metadata for SCORM requires advanced knowledge in SCORM standards (http://www.adlnet.org). Due to these limitations, the current version of EBOOK.EXE is best used as in-house development tool. A future version of EBOOK.EXE is under development that focuses on usability by a variety of trained and untrained users.

Summary

Though we have shown the use of this particular desktop based authoring tool for the HURAA project, it should be noted that any content from any domain can be utilized within the system. The ability for the Learning Management System to deliver specific content rests solely within the authoring tool and its widespread functionality. Although the system we have set-up specializes in the delivery of government policies, procedures, and guidelines, we are confident that other domains can fit within the framework of both the LMS and the content script/database set-up by EBOOK.EXE

In this paper, we introduced an approach on how to develop and use EBOOK.EXE as an authoring environment for the web-based training system, HURAA. Presently, we have explored EBOOK.EXE, a desktop based authoring tool for use with HURAA, and explained some of the design considerations we took into account during our development evolution. While we do not claim our authoring environment is the definitive model for developing authoring tools, we assert that others can build upon these ideas in the development of their intelligent and authoring systems.

We introduced EBOOK.EXE as an authoring environment for adaptable hypermedia content as our solution these challenges associated in authoring the content. Since the LMS of HURAA allows for many learning paths as well as the option of allowing the user to explore the entire system, EBOOK.EXE needed a wide array of functionality and control over the content and its delivery. This led our design to be extremely functional to a finite set of users. Using this version of EBOOK.EXE, a variety of skilled users were able to organize and structure the content of HURAA. However, our future work on EBOOK.EXE will focus on increasing the usability of the system to make it accessible to unskilled users, as well as making attempts to make the authoring more web based.

Abstract: The purpose of this study was to investigate the level of perception and satisfaction of students in online distance learning graduate courses for daytime Regular MBA (Regular) and evening Weekend Professional MBA (Weekend) programs. Distance learning delivery methods have changed over the years but not perceptions. This study attempted to identify if there are any significant differences in Regular and Weekend students' assessments of demographics, personal preferences and habits, technological proficiency and evaluations (course, online course structure, instructors) in their online course experience. This research has shown that online audio chat and text chat have a positive effect on students' learning. The data also showed that moving from traditional to online had no undesirable outcome on students. Working with students to understand the benefits, dangers and limitations helps them adjust to online course environments.

Introduction

The business world is changing and so is the delivery method to MBA students. With the recent growth and development of distance learning, online teaching has become a method of helping students to take their required load of courses even those who might otherwise provide a time conflict. As one of the predominantly African American business schools first accredited by the AACSB International (American Assembly of Collegiate Schools of Business), the Clark Atlanta University School of Business in Atlanta, Georgia (hereafter referred to as CAU Business School) changed computer based information systems courses from traditional to online. This process of development took a three-year effort.

CAU Business School has maintained the standards of a high-quality institution that produced the best-projected return on investment as a two-year MBA program, according to rankings published in Business Week (October 1998). This study discusses transitions: face-to-face meeting in the classroom (1999); one meeting in the classroom and one online with text chat (2000); no face-to-face classroom meetings, online course with text and audio chats (2001). A survey was conducted at the end of each semester. The cross tabs' statistics and measures of association (Pearson chi-square) were computed to determine if there are any significant differences between students' perceptions and satis faction with their online course experiences in Regular and Weekend programs.

Literature Review

California Distance Learning Project (CDLP) (2001, ¶ 1) in its definition of Distance Learning states, "The implementation of DL is a process which uses available resources and will evolve to incorporate emerging technologies." Martinez (September 2000) stated, "You can achieve the same instructional objectives for everyone – it's just that you do it in a different way for people with different learning orientations" (p. 40). Many universities have committed to offering distance-learning courses. According to Langford, Farinella, Weeks & Hobbs (2001, Spring), "It seems clear that the implementation of distance learning offerings has become part of the strategic commitment at many university and college campuses" (p. 75).

Distance learning has increased in the academic environment. Ron Burnett (2000), President of the Vancouver, British Columbia stated:

> In academic circles, there has been a 72 percent increase in the number of distance-learning programs, many of them Web-based courses, with 1.6 million students making use of them during the 1997-'98 academic year alone. The market is expected to grow to $1.6 billion by 2002 (p. 122).

Burnett also believes that "the combined market for corporate and academic distance learning is expected to surpass $11.5 billion by 2003" (Burnett, 2000, p. 122).

Further research is needed to gain insight into students' perceptions of online courses. With that thought in mind this research began in the Spring of 1999. The research involved offering online graduate Management Information Systems courses. Since no courses were online in CAU Business School, the researcher was given permission to pilot this research. These courses were taught in the Decision Sciences Department of CAU Business School. This paper is an account of the transition and students' perception of online courses.

Formal learning is no longer confined to a classroom or a school day. Distance Education has become the wave of present and future learning modes. According to Rex Adams, Dean of Fuqua School of Business at Duke University (2000 ¶1), "Even for top business schools, using the Internet to supplement classroom learning is a relatively new endeavor." (http://www.fastcompany.com/learning/braintrust/radams.html) Adams states "....... most of the world's best business schools are moving at full speed to take advantage of this medium's ability to extend teaching capabilities." (http://www.fastcompany.com/learning/braintrust/radams.html)

According to Culross (Spring 2000), "While few colleges and universities are likely to replace face-to-face instruction totally with computer-based instruction, more and more faculty will opt to teach online courses or to offer portions of their courses through the Web" (p. 38). Terry Neil (February 2001) stated, " With the advent of new educational and training technologies augmented by the Internet, distance learning is a viable option in meeting the needs of today's learning-hungry, but time-pressed students" (p.64). Ed Kazlauskas, Rossier School of Education states:

> ... approaches include examining distance learning from a management perspective at the macro-level, e.g. revenue streams or academic/administrative policies, from a technology perspective, e.g. web-based course management packages such as Blackboard, Mallard, and Web-CT, or from an instructional design perspective, e.g. learning strategies employed in the distance learning approach. But rather than focusing on these as a lens to examine the field, it may be more meaningful for faculty to examine distance learning in terms of the participants involved (2000-2001, ¶2).

This study involved Regular and Weekend students. Weekend program provides time pressed students with an opportunity to upgrade their skills. Weekend Professional students are more experienced and diverse. Stevens (1999) stated, "Web-based, distance-learning MBA programs give busy tech managers an opportunity to hone their business skills and knowledge while remaining at their job" (p. 31). This method of learning is not only being used by tech managers, but by working professionals as a whole.

Technology and instructions designed for students and instructor interaction in online courses can be as effective as traditional courses. Parviz & Ludwig (November 1999) stated, "Research comparing distance education to traditional classroom instruction shows that teaching at a distance can be as effective as traditional instruction" (p. 114). Student-instructor interaction by sharing information and knowledge is the key to delivering online courses. Students must be able to navigate and access information. Email communications allowed instructor to respond quickly.

Methodology

An Internet web based data instrument was developed to collect data. The survey instrument created covered six areas of interest: demographics (questions 1-5), personal preferences and habits (questions 615), technological proficiency (questions 16-21), course evaluation (questions 22-27), online course structure (questions 28-41), and instructors' evaluation (questions 42-47). The instrument was piloted on 20 randomly selected MBA students. Modifications were done and the instrument was administered over five semesters from Spring 1999 to Spring 2001.

At the end of the Spring semester 1999 the first survey was conducted. Emails were sent to the students asking for their participation in an online survey for the study. They were given a Web URL address, user name and password. The instrument required the respondents to identify the courses they took to eliminate the need to code the instrument. Submitted surveys were emailed to the researcher. One follow-up email was sent to remind students that the surveys should be completed by the last week of the semester.

Fifty-seven students in the Spring of 1999 were taught in a regular classroom setting. Twenty-seven students in Special Problems, and Systems Design and Analysis in the Fall of 1999 and 56 students in two sections of Management Information Systems in the Spring 2000 took Web enhanced courses. The Management Information

Systems course was scheduled to meet twice a week on Tuesday and Thursday. The students agreed to meet in the classroom one day and online in Cyber-Class Level Two (text chat only) published by HyperGraphics one day. Email and text chats were used as a means of communication during online sessions.

Cyber-Class was straightforward and students had no problems navigating around the site. Students used asynchronous sharing of e-mail, bulletin board exchanges as conferencing tools, which is searchable and supports the use of attachments for file exchange. It provided learning tools that helped students with concepts and updated news articles.

The students also had a chance to compete with other students from other universities in the Cyber Challenge games. Several students received scores high enough to have the university listed. It was a continuous challenge each week to see if they could get scores high enough to keep the university listed. The games contained questions dealing with the concepts in the textbook. Table 1 lists the features available in Cyber-Class.

Assignments	Audio Classroom
Hot Links (interesting links to web sites)	Text Chat (Private chat room)
Cyber Challenge (Jeopardy-like game tests your mastery of the course materials)	Company Briefs (students learn how companies use/sell technology, scoops on job opportunities plus special student discounts)
Calendar	CyberNews (vital links to CyberClass news)
FlashCards (students practice how well they understand key terms and concepts)	Syllabus
Testing (Chapter/Instructor Test)	Student Administration (user name, grades)
Student Bulletin Board	Student Guide
Sending Messages (e-mail)	Technical Support (telephone, email and live text chat from 10 AM CST – 6 PM CST Monday – Friday)
View Messages	No activity in 4 hours automatically logs students out

Table 1. Cyber-Class

In text chat students were given a question and they typed their answer. The remaining students could agree, add to or disagree with the answer given. Everyone was given an opportunity to answer a question. Bonus questions were also offered. This method was ok, but still provided a problem for students who typed slowly. Assigning questions ahead of time or letting students pick their own questions helped those who typed slowly. The students were able to type their answer ahead of time in Word or Notepad and cut and paste their answer into text chat.

A few students using AOL browser had some technical difficulties during the semester. But the difficulties did not interfere substantially with the course. Students using AOL connection had difficulties during timed exams and quizzes; sometimes the Internet provider disconnected the students. Students using AOL browsers were advised to minimize the AOL browser and open another browser for the exa ms and quizzes.

In the instructor's effort to enhance the course moving the courses from Level Two (text chat) to Level Three (audio and text chats) in CyberClass provided synchronous sharing audio chat. The instructor, student and student's classmates could hear each other speak in the audio classroom. The voice chat enabled two or more to communicate via microphone in a speaker conference call style over the Internet connection in real time.

In the Fall of 2000 and Spring 2001 sixty-one students were strictly taking distance-learning courses using Cyber-Class with both text chat and audio chat. The audio chat room was a great enhancement to the class. This allowed the instructor and students to chat once a week. It was like having a face-to-face meeting without being physically present. Students only needed a sound card and microphone on their computer. Students did not seem to have major problems in moving from a classroom setting to an online teaching method.

In the online meetings weekly chapter reading and review questions were discussed. Each student was given a question to answer. Other students were encouraged to participate once the students' answer was given. Students were encouraged to share ideas, information, articles, books and TV news. This format enhanced students' participation because they did not have to type their answers. They could answer the question using a microphone, which gave the feeling of an in-class meeting. In this format students could concentrate on concepts of the materials rather than typing. Students could also send a private message to the instructor during the audio chat meeting if they had a problem.

Audio chats allowed students to have an interactive online learning environment via the Internet. Students also used the audio chat room for team meetings. This worked out well for the students, because they could be at home and still attend their team meetings. To prepare them for distance meetings and problem solving via the Internet, the students were instructed to hold all team meetings in the text or audio chat rooms.

In the Fall of 2001 the university adopted Web-CT format. All web enhanced or distance learning online courses were switched to Web-CT. When the courses were moved from Cyber-Class to Web-CT the audio chat room enhancements were lost. Web-CT offered text chat and a whiteboard facility, which included a shared text window that supported sharing drawing. The whiteboard allowed the use of standard image formats including JPEG, GIF and BMP. This was a step backward. Audio chat room enhancements allowed the instructor to communicate with students on one-to-one basis about concepts and issues, which was not available in Web-CT.

The sample for this study included 233 MBA students in CAU Business School. Regular program offered Management Information Systems, Special Problems in Decision Sciences, and Systems Analysis and Design. Weekend program offered Information Systems II, Information Systems III and Accounting Information Systems Analysis and Design. Survey questionnaires were collected Spring and Fall 1999, Spring and Fall 2000 and Spring 2001.

Out of 233 students there were 201 (86%) valid respondents. Regular students 158 (78.6%) and Weekend students 43 (21.4%) participated in the survey. There were 81 males and 119 females ranging from 21 to over 35 in age. The chi-square test of independence was used to analyze the data.

Findings

The demographics dimensions included age groups (21 to over 35), gender (female, male), majors (Decision Sciences, Finance, Marketing) and the semesters that online courses were taken. The study indicated that age group and MBA programs are related. Question 2 (Q2) "What group best represents your age?" Regular students 3.5% are in the youngest age group of 21-24, compared to 2.3% of the Weekend. On the other hand, only 9.5% of the Regular students are in the 35 and over, compared to 32.6% of the Weekend students (p=0.000). Q3 "What is your gender?" The study showed no significant difference between Regular and Weekend students.

In Q4 "What is your major?" showed a significant relationship between Regular/ Weekend programs and majors. Weekend students 68.3% are majoring in Finance compared to Regular students 38.1%, in contrast to Weekend students Marketing 31.7% compared to Regular students 47.8% (p = 0.001). Question Q5 "What semester/year did you complete your online course?" showed a significant relationship between Regular/ Weekend programs (p = .044).

In the subgroup analysis of Personal Preferences and Habits Q6 " How many miles do you drive to the CAU campus each day?" Students drove at least 11 miles to campus Regular 67.1% and Weekend 76.8%. In Q7 "Why did you decide to take this course?" Responses to fulfill a requirement and subject seemed interesting were Regular 61.4%, 28.5% compared to Weekend 88.4% and 2.2% respectively. It was interesting to note that two courses in the Regular program were electives for most students (p = .002).

Question Q8 "What is the highest degree you plan to earn from any college or university?" There were no significant differences between the two programs. However Ph.D. was selected by 26.6% of the Regular students compared to 14.0% of the Weekend students. Q9 asked, "Which of the following best describes your reason for taking college course at this time? To advance in current position and to discover new job opportunities were Regular 2.5%, 42.7% compared to Weekend 15.8% and 28.9% respectively (p = 0.018). More Weekend students were interested in advancing in current position while Regular students were interested in discovering new job opportunities.

Respondents were asked in Q10 "How many credit hours are you currently taking?" Students in the Regular program 63.2% were taking 13-15 credit hours compared to Weekend only 10.0%. On the other hand Weekend students 82.5% were taking 7-9 credit hours compared to Regular 4.9% (p = 0.000). Regular students were on semester credit hours and Weekend students were on trimester credit hours. Question Q11 asked, "How many hours per week do you work for pay?" Weekend 62.2% spend 21 or more hours working compared to Regular 37.8%. However Regular 29.1% spend 2-10 hours a week compared to Weekend 18.9% (p = .031). Q12 asked, "On average how many hours per week do you spend on campus for classes? More than half of the Weekend students 56.3% spend 6-10 hours on campus compared to Regular 46.7%. However Regular students 42.0% spend 11-20 hours compared to Weekend students 22.8% (p =0.045).

Q13 "On the average how many hours do you spend on campus working on course assignments in the lab?" All courses required case assignments. Regular and Weekend students spend 60% and 77.5% respectively on campus working on assignments (p= 0.097). Questions Q14 "On the average how many hours per week do you spend working on team projects?" and Q15 "Requiring that students own laptop computers is a reasonable expectation of the business school" showed no significant differences between the programs.

In Q16 the statement "I can search for information on Internet/World Wide Web," Regular students 0.6% were novice users compared to Weekend 14.0%. More Weekend students 25.6% were expert user than Regular students 15.8% (p = 0.001). In Q17 the statement "I can electronically send and receive files by way of the computer (over a modem, the Internet/WWW etc.)," responses showed no significant differences between the two programs.

In Q18 "I have experience using online text chat and audio chat rooms," responses for audio chat rooms were Weekend students 28.6% compared to Regular 15.4%. On the other hand, text chat rooms were Regular students 19.2% compared to Weekend 7.1% (p = 0.048). With both programs using audio and text chat rooms, this study shows that these methods could enhance students' learning experiences.

Q19 "I feel comfortable using the World Wide Web for research purpose." and Q20 "How comfortable are you working on teams using email, text chat and audio chat rooms as primary communication tools?" were not significantly different between the two programs. Question 21 asked, "Did you have connection problems with your Internet provider? More Weekend students 44.2% responded Yes than Regular students 23.8%. Regular 76.2% responded No compared to Weekend 55.8% (p = 0.009). When the students were asked to name the providers, one Internet provider's name stood out more than others.

The following three question statements showed no significant differences between the two programs. Q22 "This course increased my knowledge and understanding of the subject matter," Q23 "This course required me to think and to analyze information." and Q24 "I understand and can apply the concepts I learned in this course."

In Q25 "This course increased my interest in the subject," Regular students 19.1% Strongly Disagreed (SD) or Disagreed (D) compared to Weekend students 7.1%. However Weekend students 85.7% Agreed (A) or Strongly Agreed (SA) compared to Regular 64.7% (p = .031). In Q26 "I found the course material challenging," Regular students 19.8% responded SD or D compared to Weekend students 4.6%. However Weekend students 69.9% responded (A) or (SA) compared to Regular 72.1% (p = .049). Q27 "I felt motivated to do my best work." showed no significant difference between the programs.

Students were asked to respond to the statement in Q28 "My course of study resulted in learning outcomes appropriate to the rigor and breadth of any traditional courses." was not significant. In Q29 "The presentation and organization of the course assignments and materials were coherent and complete." Weekend students 75.7% responded (A) or (SA) compared to Regular 65.6%. On the other hand Regular students 20.1% expressed (SD) or (D) compared to Weekend students 2.3% (p = 0.087). In Q30 "The instructor provided encouragement, support and feedback appropriate to meet my learning needs." Regular students 10.7% showed (SD) or (D) compared to Weekend students 7.0%. Regular students 71.9% responded (A) or (SA) compared to Weekend 55.8% (p = .013). It is important to give students quick responses to their questions or problems. Therefore online courses require prompt responses such as email or voice message communications.

The questions 31-38 showed no significant difference between the two programs. In Q39 "My course of study provided clear learning objectives and expected outcomes for the course." Regular 12.3% responded (D) or (SD) compared to Weekend 4.8%, while 85.7% of the Weekend students responded (A) or (SA) compared to Regular 63.0% (p = .044). The responses to Q40 "The delivery system or technology was reliable and stable" and Q41 "If all graduate students are required to have a laptop, do you think it would be fully integrated in most of your courses?" were not different between the programs.

The following three statements, Q42 "The instructor demonstrated concern and respect for students," Q43 "The instructor was patient and encouraged students' questions" and Q44 "The instructor was enthusiastic about the subject matter" did not show different responses between the programs.

The responses to Q45 "The instructor presented materials in a clear and understandable fashion" were Regular 14.2% (D) or (SD) compared to Weekend 0.0%. On the other hand Regular 72.9% responded (A) or (SA) compared to Weekend 76.8% (p = .062). Q 46 "The instructor demonstrated a thorough knowledge of the subject matter" was responded with Regular 6.6% (SD) or (D) compared to Weekend 0.0%. On the other hand Regular 83.5% students responded (A) or (SA) compared to Weekend 76.7% (p = .021). In Q47 "The instructor made effective use of relevant examples and illustrations", Regular 6.6% responded (SD) or (D) compared to Weekend 4.7%. Regular students responded 81.6% (A) or (SA) compared to Weekend 76.7% (p = 0.022).

Conclusions

Oliver (2000) stated "Evaluation is becoming increasingly important, both as a part of the design of online course and as a mechanism for quality assurance" (p. 83). This research has shown that online audio chat and text chat had a positive effect on students' learning. A quick response helps students move from traditional to online. Working with students to understand the benefits, dangers and limitations helps them adjust to online course environments. Students taking online courses had more flexibility in their schedules, immediate feedback on test scores and seemed to enjoy expanding their technology skills while learning. Participation points and bulletin board discussion keep students actively involved each week. Online instructors are more in touch with their students because they need the continuous feedback. Using the audio and text chats allows the instructors to have interactions with their students while they learn concepts and technology.

The authors have found that it is pedagogically sound to use both audio and text chats to enhance online course delivery. In an effort to better understand the effectiveness of the audio and text chats further research is needed to make sure students learning experience is positive. Research should be used to modify or make changes to online courses as we move toward more flexible and creative methods of delivering online courses.

ABSTRACT: End user searching on the Web has become the primary method of locating images for many people. This study investigates the nature of web image queries by attempting to map them to known image classification schemes. In this study, approximately 100,000 image queries from a major web search engine were collected in 1997, 1999, and 2001. A stratified sample of the queries was classified using three previously published image classification schemes. The results indicated that the features and attributes of web image queries differ relative to image queries utilized in other IR systems and user populations. Given the growing ubiquitous nature of the web, the implications for the design of information retrieval systems and repositories are discussed.

Introduction

The tremendous growth in the quantity of digital images is driving the need for more effective methods of storing, searching, and retrieving image data. With the development of such technologies, image indexing and retrieval have received increasing attention. However, there has been little research into image searching on the Web, especially how users search for images in the web environment. Given the pervasiveness of the web, the manner in which user's conduct image searches on web may also be good indications of how they will conduct future searches in other environments.

One can classify current image retrieval approaches, whether on traditional systems or on the web, as either concept or content based (Rasmussen, 1997). In the concept-based approach, image retrieval research has focused on the retrieval of images utilizing indexed image collections (Enser & McGregor, 1992; Goodrum and Spink, 1999). Researchers and practitioners have created thesauri for visual information, such as the Library of Congress Thesaurus for Graphics Materials, Metadata (Greenberg, 1993). These thesauri are then used to index images within a collection.

Conversely, in the content-based approach, the focus has been on indexing images at the pixel level and the implementation of search features using pixel comparison (Wang, 2000). Content-based image IR systems allow users to search image collections using color, texture, shape, and spatial similarity. These systems many times also provide text-based search functions for notations and text descriptions embedded within images. New technologies have placed the emphasis on content-based retrieval, with commercial systems such as the MediaSite.com (http://www.mediasite.com) system.

However, it is not clear how the retrieval functionality of either of these approaches systems correlates with the image needs of real users. Concerning the context approach, Brown, Hidderly, Griffin, and Rollason (1996) point out that experts are not a good source of terms that are preferred by real users. Concerning the content approach, Chen (2001) notes that users seldom search using content characteristics. Although user studies within specific domains have been conducted, Jansen and Pooch (2001) have shown that Web users differ in their interaction with

IR systems relative to users in other environments. In this respect, studies of the image needs of web users are especially needed for effective and efficient design of web-based, image IR systems.

The research presented in this article focuses on the information needs of web user's as represented by their image queries. Specifically, web user queries from a major web search engine are investigated. We analyze the end-user's image query structure across three periods (1997, 1999, and 2001), classify user queries using accepted classification schemes, compare the characteristics to those identified in previous studies and provides suggestions for improving image indexing and retrieval systems to meet the information need of web users.

Review of Literature

User Information Needs and Image Queries

Ellis (1984, p. 25) advocates that design of IR systems must be with "an orientation to the use and the user's interaction with information sources. Fidel [8] points out that studies in image retrieval have ignored several fundamental issues, including the differences between text and image retrieval, the image attributes important for retrieval, and the characteristics of user's image queries. These points are especially germane with respect to image searching on the web given the almost complete lack of studies in this area.

There have been some studies of image searching on the web, including Goodrumand Spink (1999) and Jansen, Goodrum and Spink (2000) that have analyzed images queries from web users as part of a review of multimedia queries. However, these studies presented primarily factual characteristics of image queries; none of these studies attempted theoretical classification of web image queries using known classification schemes. Without such research, one cannot determine whether or not the web user population's image information needs conforms to currently accepted image retrieval approaches.

Image Retrieval on the Web

In general, Web users must search for multimedia information as they would search for textual information (Schauble, 1997) with many Web IR systems providing no special mechanism for multimedia searching. The advantage of this approach is that image searching is performed in an identical manner to text searching. No additional burden is placed on the searcher. If the searcher desires an image document, the searcher enters the query and specifies some image attribute. The disadvantage of this approach is that it places more contextual knowledge burden on the searchers, who may not be familiar with image formats. Necessitating that users translate a non-textual information need into a textual query may challenges a user's cognitive load, creating a semantic gap (Gudivada & Raghavan, 1995). Excite (http://www.excite.com) and Yahoo search engine (http://www.yahoo.com) are two such Web IR systems that take this approach.

Some Web IR systems specialize in image collections or provide mechanisms for users searching for images (e.g., radio boxes or media specific search syntax). Alta Vista (http://www.altavista.com) and Lycos (http://www.lycos.com) searchers can narrow a query to specifically search for an image. ClipArt Searcher (http://www.webplaces.com/search/), the Yahoo Picture Gallery (http://gallery.yahoo.com), and Webseek (http://www.ctr.columbia.edu/webseek/) are examples of image specific retrieval applications allowing users to search by terms or select from general categories of images and video. Both Webseek and Alta Vista return thumbnail images and file names in the document result list. Webseek also provides tools for content-based searching for images and videos using color histograms generated from the visual scenes.

In terms of image indexing, most web IR systems follow a relative straight forward approach. The simplest image search algorithm locates images files by searching for file extensions, matching the filename to terms in the query (Witten, Moffat, & Bell, 1994). This may not be a good approach, especially given the move to automatic generation of image file names by applications (e.g., converting Power Point © presentations to Web pages or transferring files from a digital camera). In these cases, the file name has little to nothing to do with the image. Web IR systems may also retrieve documents that are primarily textual but that contain embedded images. In these cases, the image filename may not match the query terms, but the Web documents may contain text that does match the query terms. The assumption being that the image relates to the text.

Given the inadequate research of user image needs on the web and a lack of theoretical background for the design and evaluation of web image databases (Chen, 2001), it is logical to examine the both web image queries and present classification schemes to discover the utility of the models for the design of web-based image retrieval systems. A review of three, previously published, image query classification methodologies follow.

Enser and McGregor Classification Categories

Enser and McGregor (1992) analyzed 2,722 image queries requests on an image system with approximately half a million engravings, woodcuts, drawings, cartoons, and maps. The combined size of the collection was about 10 million images. The researchers classified these 2,722 requests in four categories: (1) Unique, (2) Unique with refiners, (3) Non-unique, (4) Non-unique with refiners. The property of uniqueness is readily applied to a request for the visual representation of an entity where the desired occurrence can be differentiated from very other occurrence of the same entity type (Enser and McGregor, 1992, p. 17). Using refiners, one can narrow these queries some degree of specifity. The researchers point out that almost 70% (1905) of the queries were for a unique person, object or event, and 34% (925) of the queries were refined, mostly by time.

Jorgensen 12 Image Attribute Classes

Jorgensen (1998) conducted a study with 107 first semester library science students with a variety of undergraduate majors. The study participants viewed 6 projected color images that were randomly selected from *The Society of Illustrators 25th Annual of American Illustration*. The participants described the 6 projected images, and Jorgensen then classified the descriptions into the 12 classes of image attributes.

Chen's Categories and Attributes Modifications

Chen (2001) collected 534 queries fom 29 college students majoring in art history, using pre-search and post-search questionnaires. The art course students utilized an image collection containing over 75,000 volumes and subscriptions to over 200 journals in relevant fields. The collection also contained significant holding in several art related fields and facsimile collections of medieval manuscripts and original scrolls. Chen did not, however, focus on whether or not the queries were utilized on an image retrieval system. Chen mapped the queries to previous query classification methods, including Enser and McGregor (1992) categories, combining some of Jorgensen (1998) attribute classes. Based on Chen's analysis, the researcher proposed modifications to Enser and McGregor (1992) categories.

The next section of the paper describes the research design used in this study.

Research Design

This research reports the analysis of image queries from a major web search engine. The objective was to examine these image queries from real web users with real information needs, mapping these queries to known image query classification features.

Research Questions

The following research question is addressed: Can web image queries be effectively mapped using previously identified image classification schemes?

Background

The Web is an immense repository of image information (Lesk, 1997). The hypertext transfer protocol (HTTP) lends itself to the easy transfer of audio, video, and image formats integrated with textual information. Lawrence and Giles (1999) estimated there are 180 million images on the publicly indexed Web and 3Tb of image data, not including other types of multimedia files, such as audio and video. As such, the web is an immense, heterogeneous image collection.

Research Procedure

A total of approximately 100,000 image queries from the Excite search engine (http://www.excite.com) were collected in 1997, 1999, and 2001. Each transaction record contained three fields. With these three fields, one can locate a user's initial query and recreate the chronological series of actions by each user in a session:

1. **Time of Day**: measured in hours, minutes, and seconds from 00:00:01.
2. **User Identification**: an anonymous user code assigned by the server.
3. **Query Terms**: exactly as entered by the given user.

Overall, the metrics used in this research are as defined in (Jansen & Pooch, 2001). We defined the session, query, and term variables as:

1. **Session**: A session is the entire series of queries by a user over time, from one query to many.
2. **Query**: A query consists of one or more search terms, and may include logical operators and modifiers.
3. **Term**: A term is any unbroken string of characters (i.e. a series of characters with no space between any of the characters). The characters in terms included everything – letters, numbers, and symbols.

Founded in 1994, Excite, Inc. was a major Internet media public company that offers free Web searching and a variety of other services. It has since been purchased and is no longer an independent company. Excite searches were based on the exact terms that a user enters in the query; however, capitalization is disregarded, with the exception of logical commands AND, OR, and AND NOT. Stemming is not available. An online thesaurus and concept linking method called Intelligent Concept Extraction (ICE) was used, to find related terms in addition to terms entered. Search results were provided in a ranked relevance order. A number of advanced search features were available. A page of search results contained ten answers at a time ranked as to relevance. For each site, the results list provided the title, URL (Web site address), and a summary of its contents. A user could click on the title to go to the Web site. A user could also click for the next page of ten answers.

Content Analysis

A set of 587 image queries was randomly selected from one of the transaction logs. The image queries were then categorized using each of the three classifications schemes discussed previously. A query could be mapped to more than one feature or attribute. Therefore, the number of mapping incidents may be greater than the number of queries. We now present the findings of our research.

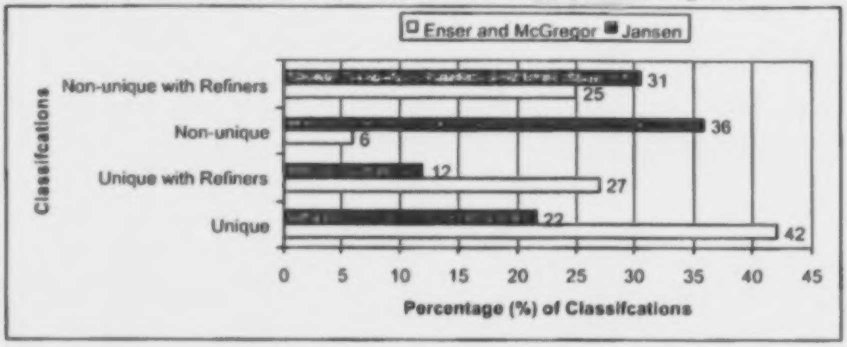
Research Findings

We analyzed to what degree does the image queries map to previous identified image query features, categories, and image attributes. A set of 583 image queries was randomly selected from one of the transaction logs and then mapped to each of following classification schemes.

Mapping Results using Enser and McGregor's Categories

The image queries were mapped to Enser and McGregor's image categories. The overall results are displayed in Figure #1.

Figure 1: Mapping using Enser and McGregor's Four Categories

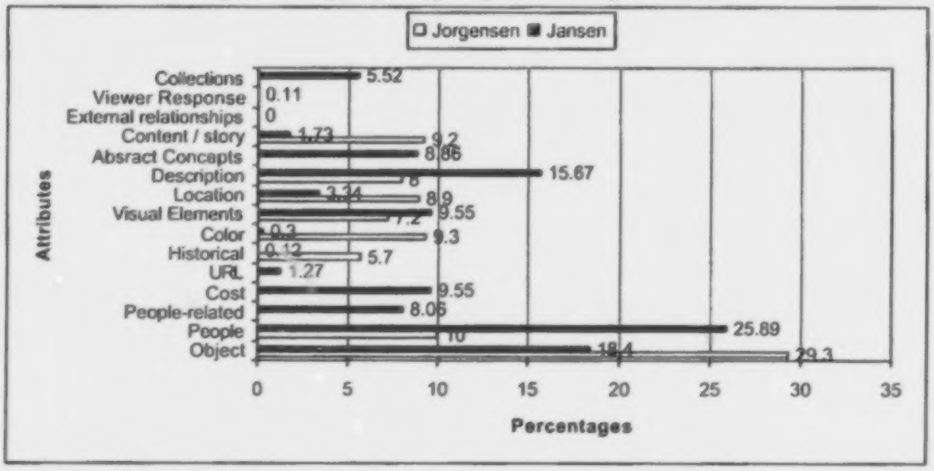


The total number of judgments for the study of Enser and McGregor's was 583. From Figure #1, one can see that the percentage of requests for unique image information was substantial lower on the web than reported by Enser and McGregor's, and naturally, the percentage of non-unique request was higher. Perhaps surprising, given the antidotal comments concerning web users, the use of refiners was quite high, comparable and even exceeding that reported by Enser and McGregor.

Mapping Results using Jorgensen's Image Attributes

We classified the image queries to Jorgensen's image attributes. The overall results are displayed in Figure #2.

Figure 2: Mapping using Jorgensen's image attributes.



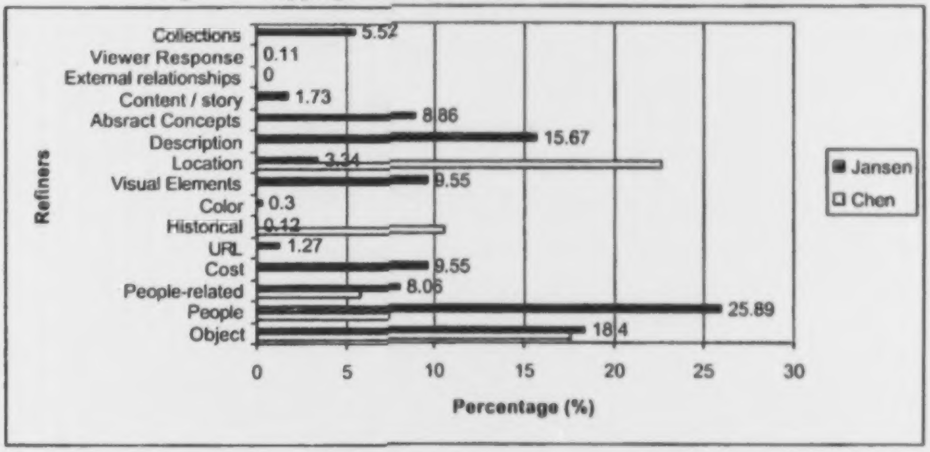
The total number of judgments for the study of Jorgensen's image attributes was 869. Jorgensen's original 12 attributes did not effectively describe the attributes of the web image queries, so an additional three attributes were added, namely cost, URL, and collections. Concerning the three attributes added, it is apparent that cost is factor with web users, a fact that would not be apparent in lab studies using students, as Jorgensen and others have done. Given the unique hypertext environment, the location of the images is apparently a concern of Web users given the high number of URL requests and searches for images collections. People and people – related queries seem to dominate the information needs of web users. Content-based attributes, such as color, do not appear to be utilized by web users even though web IR systems provide relevant results to these content-based attributes (e.g., using Alta Vista, search for blue images).

BEST COPY AVAILABLE

Mapping based on Chen's Modifications

We classified the image queries to Chen image categories modifications. The overall results are displayed in Figure #3.

Figure 3: Mapping using Chen image categories modifications



The total number of judgments for the study of Chen's image attributes modifications was 869. Similar to Jorgensen's scheme, we had to add attributes to account for differences in the web query. The results from the web mapping was much more diverse than that reported by Chen.

Discussion

In Enser and McGregor's study (1992), approximately 70% of the queries were for a unique person object or event. Also, 34% of these requests were refined, primarily by time. In applying the Enser and McGregor's categories to web image queries, we find that the majority of queries were non-unique, but almost all of these were refined in some manner, with cost (24%), presentation aspects (20%), or pornographic (16%) refiners being the most common.

In the Jorgensen study (1998), the literal Object class held the highest position in the searching task (29.3%), followed by the people class (10.0%), and then the color class (9.3%). In the analysis of web queries, the most frequency occurring attribute is People (26%), followed by Description (16%) and then Object (18%).
In the Chen study [4], the 29 searchers mainly utilized unique terms and seldom used refiners. Chen identified five refiners, which were Object, People, Historical, and Location. The web queries correspond to these five categories but there are also substantial numbers of cost (10%), Visual Elements (10%), Description (16%), Abstract Concepts (9%), and Collections (6%).

Conclusion

How users search for images on web is certain to have an impact on how users interaction with other knowledge bases. Thanks in part to the Web, end user searching is now the primary method of locating images for many people. This study investigated web image queries. By mapping a sub-set of image queries to known image classification schemes, the results indicated that the features and attributes of web image queries differ relative to image queries utilized in other IR systems and user populations. The majority of image queries were requests for non-unique entities and almost all contained some refiner. Cost is the most prevalent refiners. Most image queries are for people. Despite these differences, it is apparent that known image classification schemes can be modified to account for the characteristics of web users.

BEST COPY AVAILABLE

In future research, larger sub- sets of web images queries will be provided to multiple reviewers in order to obtain inter rater reliabilities. In this respect, we model off of the technique used by (Chen, 2001). We expect this technique to refine our classification attributes. From this, one can derive a meaningful scheme for classifying web image queries.

Abstract This research begins to refine a cognitive model of interactive information seeking for use in the design of information retrieval (IR) systems. The research reported in this article critically examines several interactive information seeking and retrieval models that have emerged over the last two decades. Building primarily on the stratified model, interactions are identified at the surface stratum that can be utilized to design information retrieval systems that infer intentions at other strata, thereby better assisting users during the search process. This paper presents the development technique utilized to modify an existing IR system that monitors these interactions and recommends search tactics to the user. The result is an increase in the performance of an IR system, as measured by precision.

Introduction

This research begins the refining a cognitive model of IR searching to a level of granularity useful in the design of an IR system. End user searching on traditional information retrieval (IR) systems, on-line public access catalogues, Web search engines, and digital libraries has become the primary method of locating information for many people. With the advent of end-user searching, numerous cognitive models of information seeking and retrieval have been proposed. Unfortunately, many of these cognitive models seem to be in a perpetual state of early development and have not taken the next, critical step in refining the models. Presently, many IR cognitive models are not sufficiently developed for the design of IR systems, with the result that current systems may not effectively or efficiently support users' information seeking needs.

This article begins with a review and critique of cognitive models for information seeking and retrieval. One model that is discussed at some length is the stratified model. Building on this model, modifications to the surface stratum that take advantage of the entire range of user – system utterances, not just the query, are presented, along with how these interactions relate to the user's cognitive and situational strata. A development technique is presented to utilize these interactions in the design of an IR system. An existing IR system is modified using this approach. The article contains a discussion on the improved system, the results of a user evaluation, and then concludes with recommendations for future research.

Related Research

Cognitive models have been successfully utilized in human – computer interaction, and research is now underway to incorporate cognitive models within sets of design tools (Ritter, et. al., 2001). However, research into cognitive models of interactive searching on IR systems is still at an incipient stage, despite a large body of research on user – system interaction. Researchers have investigated many aspects of interactive searching, including queries, search terms, sessions, and feedback, among other factors (Saracevic, et. al., 1988; Saracevic, et. al. 1991; Spink & Saracevic, 1997).

However, Ellis (1984) has pointed out the flaws of attempting to develop a theoretical searching model utilizing this approach. These empirical studies have focused on the observed elements of searching as it currently is exhibited, usually taking a grounded theory approach (Strauss & Corbin, 1990). The data gathered in these studies may not translate to other user populations or IR systems. In this respect, the "knowledge derived from the testing is uncertain" (Ellis, 1984, p. 25). As Ellis predicted, indications are that the results from these studies are only specific to a particular IR environment (Jansen & Pooch, 2001). Because of these potential shortcomings, a theoretical approach to IR research on user – system interaction is needed (Saracevic, 1996).

From a theoretical approach, there are numerous cognitive models of interactive IR systems (Bates, 1979; Belkin, et. al., 1989; Ellis, 1997; Ingwersen 1996; Saracevic 1997). All have similar goals, usually to (1) document the interaction between the user and IR system, (2) identify patterns, (3) relate the patterns to retrieval effectiveness, and (4) incorporate those patterns that will increase the performance of IR systems into the designs of IR system mechanisms (Saracevic, 1996). However, no one has yet sufficiently developed any of these models to a level where one can conduct empirical tests or utilize them for IR system design (Saracevic, 1997; Spink, et. al., 1998). In fact, Ellis (1992) points out that it is difficult to identify "any particular achievement which stands out as exemplar" (p. 52) using the cognitive modeling approach to IR. Almost a decade later, Ellis's statement is still valid. Some of the many cognitive models are discussed and critiqued below.

Traditional IR Model

As presented by Robertson (1977), the traditional IR model contains a system and a user. The system has several information objects that are organized in some manner. The user has an information need that is represented by a query acceptable to the system. The system performs the matching between the query and the information objects, presenting the results to the user. There is a feedback function that allows for the user to modify the query based on the previous results list. Although the traditional model addresses a component of the search process, there are several weaknesses. For example, the model assumes that the query accurately represents the user's information need. The traditional model also fails to consider users' cognitive needs, user behaviors, interactive searching, and user gaps in knowledge (Spink, et. al. 1998).

Cognitive Models of Interactive IR

As end user searching continues to proliferate, several cognitive models specific to interactive IR have been proposed, including those derived from observed user behaviors during the information seeking process. Bates (1979) presents several search tactics grouped as monitoring, file structure, search formulation, and term. Bates suggests that the collection of these tactics represents a model of IR seeking with users adopting different tactics for different information needs or environments. However, similar to the traditional model, these different tactics fail to consider actual user needs, situations, knowledge gaps, and disconnections between the system and user.

Bates (1989) suggests a berry-picking model of information retrieval where the information is scattered around like berries around bushes. The information need is not satisfied by a single set of results but rather by selecting a series of information bits along the way. The information need as represented by the query is continually shifting as the user moves through a variety of information sources. As the user discovers new information, new ideas and directions of search may emerge.

Although anecdotally, one can relate the IR process to this berry-picking model, from a system design perspective, there is not enough detail to develop IR. For example: What is a berry? How is it different from non-berries? How does the user distinguish the berries from the non-berries? What are the causes for the changes in directions? How can these causes be coded? How is the model to be evaluated within the accepted IR metrics of recall and precision?

Cognitive Models of IR in Hypertext Environments

With the Web affecting almost every facet of information seeking, several cognitive models specifically addressing a hypertext environment have emerged. Marchionini (1995) proposes a model, based on the behavioral model of Ellis (1989) but accounting for the browsing aspects of hypermedia environments. In the Marchionini model, the information seeking process is composed of eight sub-processes that develop in parallel

(Marchionini, 1995, p. 49-60). The eight sub-processes are: (1) *Recognize and accept an information problem*, (2) *Define and understand the problem*, (3) *Choose a search system*, (4) *Formulate a query*, (5) *Execute search*, (6) *Examine results*, (7) *Extract information*, and (8) *Reflect, iterate, and stop*. Unlike Ellis's version (1989), this model describes a process rather than independent behaviors; however, the issues of implementation in the design of an IR system still remain.

A web user 'taskonomy' (Byrne, et. al., 1999) has taken a grounded theory approach to classify logical groupings of information seeking tasks on the Web. This model identifies six main categories of user actions within a hypertext environment, which are:

- *Use information*: Read, view, listen, save to disk, duplicate, print, etc.
- *Locate on page*: Something "interesting," related concept, tagged information, etc.
- *Go to page*: Hyperlink, back, forward, bookmark, check history list, provide URL, etc.
- *Provide information*: Search string, shipping address, survey response, etc.
- *Configure browser*: Add bookmark, set helpers, change cache size, scroll, etc.
- *React to environment*: respond to dialog, respond to display change, reload, etc.

Choo and Turnbull (2000) examined information seeking behavior of information managers on the web to develop a model of browsing and searching, and Kalbach (2001) has developed specific design criteria using this web model; nevertheless, how these criteria and suggestions relate to the overarching model is not clear. However, in the end these models of hypertext IR seem more a collection of empirical, grounded theory observations. The suggested design criteria appear to be mainly the application of accepted engineering psychology, human engineering criteria, and software engineering practices.

Stratified Model of IR Interaction

One of the more developed models is the stratified model (Saracevic, 1996). Theoretically, it draws on communication concepts in human – computer interaction and stratification theory in linguistics and communication. The stratified model views the interactive-searching process as a dialogue between participants, which are the user and the computer system. The dialogue is defined as a sequence of events in time toward some result. Each of the participants, user and system, has different levels or strata. Interaction is defined as the interplay between various strata over time. The dialogue occurs within these connected strata, converging at the surface stratum. The exchange of information between participants in the dialogue occurs through an interface at a surface stratum.

Saracevic (1996) discusses three strata for the user, which are: situational, affective, and cognitive. At the situational stratum, the user interacts with the given situation or problem that produced the information need. The results of the search may be applied to a resolution of the information need. The situation was the reason for the interaction to start, and the situation may be ill defined. A user brings given states of knowledge, belief, intent, and motivation to the situation. These states may change during the dialogue.

On the affective stratum, users interact with their intentions and associated elements, such as beliefs, motivations, feelings, desires, and urgency.

At the cognitive stratum, users interact with the documents and information as cognitive structure. Cognitive processes at this stratum include interpretation, judgment, assimilation, relevance, and effects of changes in the state of knowledge. From an IR perspective, relevance is a key element at this stratum.

The strata on the computer side are engineering, processing, and content. The engineering level is the hardware along with the system's operational and design attributes. The processing level focuses on the software, especially the algorithms and approaches that underlie the system's IR processes. The content stratum concentrates on the information resources and their representation as made by the system.

The cognitive, affective, and situational aspects from the user strata and the engineering, processing, and content aspects from the system strata converge at the surface stratum, where the user makes utterances and receives responses through the system interface. At the surface stratum, the user engages in searching, matching, browsing, navigating within and among information resources, and reviewing results. On the system side, the system interacts with the user and provides responses in this dialogue. As the dialogue progresses, the situation at the surface stratum changes as new search terms are added, old tactics abandoned, and new tactics utilized.

The strength of the stratified model, relative to other cognitive models in IR, is that it decomposes the interactions into different strata, and it simultaneously separates the different participants within each stratum. This method of decomposition permits the design characteristics to be more easily developed once each of the various components are isolated. One can view each component as a separate object with its own set of characteristics, which lends itself to coding and component design. Saracevic (1997) points out that a weakness of the stratified model, however, is the decomposition of the various strata.

Certainly decomposition is difficult at the cognitive, affective, and situational strata. However, what occurs at these strata may have little impact on the search process if it is not expressed at the surface stratum. From a system design view, concentrating on the actions that occur at the surface stratum and then relating these back to cognitive and situational levels may in part circumvent this shortcoming of the model. In the research reported here, the concentration for refinement of the stratified model is on these utterances at the surface stratum.

Conceptual and Theoretical Framework

Further development of the stratified model in order to aid IR system design must address at least three questions, which are modifications of questions raised by (Saracevic, 1996):

(1) What are the interactions occurring at the surface stratum?
(2) What do these interactions indicate about the cognitive, affective, and situational aspects of the user?
(3) How can the system utilize these interactions to improve performance?

With respect to question one, at the surface level, the stratified model currently focuses almost exclusively on the query, although mention is made of other interactions. This focus is similar to other cognitive models. For example, in the cognitive model (Ingwersen, 1992), the query is the exclusive exchange at the interface level. The stratified model also implies the dominance of the query by referring to 'utterances' at the surface level. In (Saracevic, 1997), the query is the only element depicted that summarizes elements from other strata of the user, and Saracevic states that the "query is the most important aspect of user modeling" (Saracevic, 1997, p. 323). However, investigations at the surface stratum can concentrate on other interactions between the user and the system.

Reviewing empirical studies of interactive searching, one finds the query only one of many actions that the user takes when interacting with information objects. Marchionini (1995) notes that the user examines results and extracts information. Byrne et al. (1999) notes that the user takes several actions, including reading, viewing, listening, saving, duplicating, and printing. In a hypertext environment, the user also goes back, goes forward, bookmarks, and views the history list. These actions are expressions of the user's reaction to the information the system presents. Some expressions may be positive; others negative; others neutral, and other actions may express states of uncertainty. There are some actions that obviously stand out as positive expressions of the relevance of the information presented. These include bookmark, copy, duplicate, print, and save.

If the IR system could utilize these positive expressions of relevance at the surface stratum, both the document that caused the expression and the query that presented the information object, the system would have additional information to assist the user in locating other relevant information. This assistance could include offering searching advice or suggesting other documents that match the query, among many other types of asssitance. If desired, the user could review and process this system-provided information, which could perhaps change elements at the user's cognitive, affective, and situational strata.

This is the approach taken in this research. The aim is to design an IR system that monitors for positive expressions or utterances of relevance by the user concerning the information presented during the search process. Based on these positive utterances, the system then presents to the user courses of action, also utterances, to satisfy the user's information need.

Research Design

We utilize the agent paradigm to imbue a fully functional IR system, MG (Witten, Moffat, &Bell, 1994) with (1) the ability to monitor user utterances at the surface stratum and (2) the ability to make utterances to the user on courses of action to improve the search process.

Interactive sessions between searchers and IR systems are typically extremely short both in terms of the number of queries and time (Silverstein, et. al., 1999) and user interests are extremely varied (Jansen, Spink, and Saracevic, 2000). A method of rapidly recording the user's utterances, drawing inferences from these actions, and presenting utterances back to the user was needed.

To accomplish these aims, a technique used in adaptive hypermedia systems in which the user's information need is represented by of a set of pairs (*c*, *v*) where *c* is a concept and *v* is a value (Eklund & Brusilovsky, 1998) is modified. A concept is an idea, a subject, a preference, a submission or a topic. A value is a measure that associates the user to that concept, such as a Boolean or a numeric indicator.

This approach is altered for use in extending the stratified model. A series of action - object pairs (*a*, *o*) represents a user's pattern of utterances during a session. The agent currently monitors the surface level for five actions (*a*), stated as *a* is an element from the set {bookmark, copy, print, save, submit}. There are currently three objects (*o*) that the agent recognizes, stated as *o* is an element from the set {documents, passages from documents, queries}.

The valid object in the *(a, o)* pair varies with the type of action. Document objects are applicable to the actions of bookmark, print, and save. Passage objects are applicable to the action copy, and query objects are applicable to the action submit. For example, if a user bookmarks a file (e.g., Readings in IR), the *(a, o)* pair would be (*bookmark Readings in IR*). The agent records the series of *(a, o)* pairs during a session, and then offers assistance based on the series of *(a, o)* pairs recorded. Using this approach, one can model the user's information desires relatively rapidly.

Assistance Offered by the Agent

It was necessary at this stage of the research to narrow the agent's assistance, given the scores of user – system interaction issues (Borgman, 1996; Yee, 1991). The agent focuses on five areas of assistance, which are modifications to query structure, spelling corrections, synonyms and term context, changing the query to either increase or decrease the results list, and term relevance feedback. The agent communicates with the user via an interface button. The user can view the agent information or ignore the feedback notification with no impact on the normal operation of the IR system.

Empirical Test

To evaluate whether or not the utilization of utterances at the surface level could improve system performance, the performance of the MG system and the MG – agent system was contrasted. No MG code was modified to integrate the agent other than establishing the application program interface. The MG and the MG-agent system ran on the same computer, displayed the identical interface, and utilized the same document collection. Both systems were installed on a SPARC book 3 running Solaris 2.5. The subjects for the evaluation were 30 freshman college students, 26 males and 4 females. The document collection utilized for the testing was the Text Research Collection (TREC), volumes number 4 and 5, which are approximately 2GB in size and contain approximately 550,000 documents.

Viewing this evaluation as a preliminary evaluation, two TREC topics were chosen, *Number 301: International Organized Crime* and *Number 340: Land Mine Ban*. There were 555 relevant documents (1%) in the collection. For this research, the interest was the agent's effect on precision within the top 20 ranked documents. Thus, if more than 20 documents were returned for a particular query, documents numbered 21 and higher in the results list were ignored. If the query returned fewer than twenty documents, that number was utilized to calculate precision for that particular query.

The 30 subjects utilizing the two search topics and both IR systems generated 175 unique queries. There were 81 unique queries executed on the MG system and 94 unique queries executed on the MG – agent system. Each session was five minutes in duration. All searchers utilized the agent feedback at least once during the session. Precision for each set of unique queries executed on each system was calculated and analyzed, utilizing the documents that the user identified as relevant and the TREC relevant documents. Our analysis revealed a difference between the two sets of queries (paired $t = -3.417$; $p < 0.01$), with the precision of the MG – agent system performing significantly better than the precision performance of the base system. However, the performance of both systems was less than desirable (precision = 10% for the MG and 30% for the MG –agent system). Further evaluation will be needed for statistically meaningful results (e.g., more topics, longer sessions, etc.).

Conclusion and Significance of Research

In refining the stratified model, utterances at the surface stratum that shed light on the cognitive, affective, and situational strata during the information retrieval process were identified. An IR system was successfully modified to use these surface utterances to assist the user in the search process. The (*a*, *o*) development technique permitted the extrapolation of user notions of relevance based on utterances at the surface stratum. Utilizing the (*a*, *o*) pair model, the agent provides this searching assistance solely from using the normal actions of a searcher during the session. The user performs no additional actions during the search process to obtain this assistance. Evaluation of the modified system demonstrates that implementation of the stratified model may be a feasible avenue of research and may lead to improved support of IR systems during the searching process.

The next step is to refine the types of assistance provided and relate specific utterances to specific information needs. The danger is in increasing the type of searching assistance too much. Although one might assume that as searching features increased so would system performance, Saracevic and Kantor (1988) have shown that the increased use of advanced features may have an adverse effect on search performance.

The (*a*, *o*) pair model of user system interaction is being refined. Jansen, Spink, and Saracevic (2000) classified search–user interactions on a web system and isolated sequencing of action. Spink, Jansen, and Ozmultu (2000) also examine the sequence of users actions on web systems, focusing on relevance feedback. By relating these utterances to the cognitive, affective, or situational strata, the hope is to further develop the (*a*, *o*) pair model to identify session patterns in addition to individual utterances during a session.

The research presented in this article is the first step in implementing a cognitive model of interactive IR. Overall, the results of the research conducted so far are promising. They indicate that the stratified model of IR can be refined to a granularity that can positively affect system design. Using this model in conjunction with advanced computer technology, IR systems can become active participants in the information-seeking dialogue.

Abstract Studies show that the majority of Web searchers enter extremely simple queries, so a reasonable system design approach would be to build search engines to compensate for this user characteristic. One hundred representative queries were selected from the transaction log of a major Web search service. These one hundred queries were then modified using the complex search operators supported by 5 major search engines. Overall, 1900 queries were submitted to five Web search engines, returning 18,256 documents. The results obtained using the complex queries from each search engine were compared to the results obtained by the original 100 simple queries from that search engine. In general, increasing the complexity of the queries had moderate effect on the results, with an average 66% exact match between results from the simple and complex queries. Implications on the effectiveness of current Web search services, for future search engine design and for future research are discussed.

Introduction

Searchers rarely use advanced techniques, such as Boolean operators or phrase searching, (Borgman, 1996) when using information retrieval (IR) systems. This characteristic has been especially true for Web searchers, with the vast majority of Web queries containing no advanced query techniques. Several Web studies have noted this near absence of complex query operators (e.g., AND, OR, NOT, must appear operators, paraphrases, etc.) in Web queries (Hoelscher, 1998; Jansen et al., 2000; Keily, 1997; Silverstein et al., 1999). The use of Boolean operators, typically about 8%, in these Web searching studies is lower than the rates reported in studies of searchers using traditional IR systems such as DIALOG or LEXIS/NEXIS, sometimes substantially. For example, Siegfried et al. (1993) reported Boolean usage of over 36% on the DIALOG system, which the researchers considered a low rate of usage.

Many IR professionals would probably say that the correct use of advanced searching operators would increase the effectiveness of Web searches. Advanced searching techniques are well known, and one can find numerous articles and books on advanced searching strategies (Korfhage, 1997), tutorials on searching training (Sullivan, 2000), and numerous educational courses on searching strategies. Many of these techniques (e.g., phrase searching and must appear operators) are easy to employ. However, based on the Web searching studies, it appears that the majority of Web searchers continue to use very simple queries, with little to no use of advanced searching operators. These searchers seem to be employing an ineffective and inefficient strategy for finding information.

This line of reasoning leads to the to the question: Why aren't Web searchers using more advanced queries? Some researchers have stated that Web searchers are just lazy (Kapur and Zhang, 2000) or that there is a design flaw with Web search engines (Clark, 2001).

Neither of these assertions seems likely. Studies and data suggest that Web users may be finding the information they want using these simple queries. A survey of users on a major Web search engine reports that almost 70% of the searchers stated that they had located relevant information on the search engine (Spink et al., 1999). Additionally, Web search engines continue to attract large numbers of Web searchers. Of the top ten Web sites in terms of number of visitors, in June 2000, eight were Web search engines (CyberAtlas, 2000), implying at least that search engines are the best alternative available for finding information on the Web. Obviously, something is amidst. Web searchers are not utilizing advanced searching operators, but they appear to be finding information using a technique that should be ineffective or at least inefficient. Although Web search engines are providing seemingly naive methods for searchers to employ, they still continue to attract a large number of customers.

To shed some light on these apparent paradoxes, we investigate the effect of complex queries (i.e., those using advanced syntax, such as Boolean operators) on the results retrieved by Web search services relative to the results retrieved by simple queries (i.e., those with no advanced syntax). Our research aim is to investigate (1) what would the effect on search engine results be if Web searchers used more advanced searching techniques, (2) whether or not the use of complex queries would be helpful for the typical Web and (3) by implication, whether or not Web search engines are somehow compensating for the simple searching techniques of Web users. We present an overview of Web searching, the study methodology, and research results from various perspectives, followed by conclusions.

Research Design and Methodology

Overview

One hundred queries were randomly selected from a transaction log of a major Web search engine. These hundred original queries, referred to as simple queries, contained no advanced query operators. Each simple query was initially submitted to a Web search engine; the query was then modified using an advanced query operator supported by that particular search engine. The results from the complex query were then compared and contrasted to the results from the simple query. The query was modified for each advanced query operator supported by the search engine. The modified queries are referred to as complex queries. The process was repeated for each of the 100 simple queries. This entire process was performed on five Web search engines.

Selection of Queries

Key to the success of this research was the selection of queries that accurately reflected the structure of Web queries. Research shows that Web queries generally have two terms (Jansen et al., 2000; Silverstein et al., 1999), cover a variety of topics (Wolfram, 1999), and are primarily noun phrases (Jansen et al., 2000; Kirsch, 1999). These criteria were used in selecting queries from an Excite search service transaction log. Specific Web query lengths reported by Jansen et al. (2000) are listed in Table 1.

Table 1: Query Length.

Terms in query	Number of queries	Percent of all queries
More than 6	1018	2
6	617	1
5	2,158	4
4	3,789	7
3	9,242	18
2	16,191	32
1	15,854	31
0	2,584	5
Total	51,453	100

The mean for query length (i.e., the number of terms in the query) was 2.21 terms with a standard deviation of 1.05 terms. These statistics are in line with those reported by other Web studies (Kirsch, 1999; Silverstein et al., 1999).

Based on the general distribution from Table 1, the queries of the following lengths were selected for this study: 10 queries of 4 terms, 31 queries of 3 terms, and 59 queries of two terms. The terms from the original queries were all lower case. Queries were selected to ensure a variety of topics since it has been reported that some search engines specialize in certain subjects (Neilsen/NetRating, 2000). Queries that appeared on the popular query lists (Searchwords, 2000) or that referenced popular entertainers, popular locations, popular songs, etc. were eliminated since Web search engines sometimes cache results from these highly queried topics (Lesk et al., 1997). For similar reasons, all queries that were obviously queries for pornography were eliminated. These goals and constraints were the guidelines for selecting the 100 queries.

Along with selecting the queries, there was also the question of what results to compare. Studies show that most Web searchers, usually about 80%, never view more than ten results (Hoelscher, 1998; Jansen et al., 2000; Silverstein et al., 1999). Based on this overwhelming evidence of Web searcher behavior, only the first ten results in the results list were selected for comparison. Moreover, we examined these results only for changes in the first ten results; relevance judgments were not made concerning the results. The ability of Web search engines to successfully retrieve relevant documents has been investigated several times (Leighton and Srivastava, 1999; Zumalt and Pasicznyuk, 1998).

Searching Environment

Many Web sites offer searching capabilities; however, this research focuses specifically on Web search engines. Search engines are the major portals for users of the Web, with 71% of Web users accessing search engines to locate other Web sites (CommerceNet/Nielsen Media, 1997). One in every 28 (3.5%) pages viewed on the Web is a search results page (Alexa Insider, 2000). Search engines are, without a doubt, the major IR systems of the Web. There are approximately 3,200 search engines on the Web (Searchengine Watch, 2000); however, only a handful of these dominate the market in terms of Web traffic. Among the better known, and those utilized in this research, are Alta Vista, Excite, FAST Search, GoTo, and Northern Light.

Searching Rules

These five search engines offer a variety of advanced searching options. Some searching options are available from each search engine's main search page. For other searching options, one must go to a 'power' searching page. For this research, only those advanced searching options available from the search engine's main page were utilized. Of the five search engines, two offer four advanced search options (+, ", AND, and OR) from the main page. Three search engines offer two advanced searching options (+, and "). All of the search engines offer dropdown boxes (e.g., language of results, document collections to search) for refining the search. When dropdown boxes were present on the main search page, the default options were utilized.

Research Structure

Each of the 100 original queries was submitted to the five search engines for a total of 500 queries. The query was then modified with the advanced searching operators supported by the various search engines. The entire process, of submitting the simple and advance queries, took 5 minutes or less. For example, the simple query *palomino horse breeder association* could be modified using the must appear operator *(+palomino +horse +breeder +association)*, phrase searching operator (*"palomino horse breeder association"*), the AND operator (*palomino AND horse AND breeder AND association*), and the OR operator (*palomino OR horse OR breeder OR association*). These modified queries are the complex queries.

Results

Of the simple queries, 498 returned at least 10 results. One query returned 3 results, and one query returned no results. Therefore, there were 4983 results to use as the baseline (i.e., 498 x 10 + 3). As mentioned earlier, results that appeared higher than 10 in the results list were not utilized.

There were a total of 1400 complex queries submitted. With each search engine offering different search options, the number of complex queries varied for each search engine, as outlined in Table 2.

Table 2: Number of Queries by Search Engine and Operator.

Search Engine	**Total Number of Queries**	**Number of Simple Queries**	**Number of Complex Queries**	**Search Options Supported and Number of Queries**			
				+	**"**	**AND**	**OR**
Alta Vista	300	100	200	100	100		
Excite	500	100	400	100	100	100	100
FAST Search	300	100	200	100	100		
GoTo	300	100	200	100	100		
Northern Light	500	100	400	100	100	100	100
Total Queries	1900	500	1400	500	500	200	200

From Table 2, all search engines supported the must appear (+) and phrase searching (") operators for a total of 1000 queries. Excite and Northern Light support the Boolean operators AND and OR for a total of 400 queries. Submission of each set of queries on a given search engine took about 5 to 10 minutes. Therefore, the opportunity for the index on a given search engine to change during the test was limited.
Table 3 presents data on the number of results returned.

Table 3: Results from Complex Queries Results

Number of Results	**Number of Occurrences**	**Number of Results**
10	1,325	13,250
9	0	0
8	2	16
7	1	7
6	5	30
5	1	5
4	4	16
3	2	6
2	3	6
1	13	13
0	44	0
Total	1,400	13,349

Of the 1400 complex queries, 1325 returned ten or more results. There were 31 queries that returned fewer than ten results but more than zero results. There were 44 queries that returned no results. Altogether, there were 13,349 results returned by the complex queries. Combined with the 4,983 results from the simple queries, a total of 18,332 results were used in the analysis.

The match had to be exact when comparing the results between the simple and complex queries; that is, the documents listed had to be the identical page at the same site. Different pages from the same site were not counted as matches. The identical pages at different sites were not counted as matches. Furthermore, if results appeared in both lists but in a different order, they were counted as matches as long as both were displayed in the first ten results.

Simple Versus Complex Query Comparison

The aggregate results of the analysis of the 18,256 results are displayed in Table 4.

Table 4: Comparison of Simple versus Complex Queries on Major Web Search Engines.

Category	Average Number of Results that Appear in Baseline	Standard Deviation	Mode	Paired sample t
Simple Queries	9.99	0.03	10	-
Complex Queries	6.55	3.77	10	40.287
				p < 0.01

The baseline mean for the simple queries was 9.99, and the mean for the complex queries was 6.55. This means that, on average, 6.55 of the ten results retrieved by the complex queries also appeared in the baseline results for the corresponding simple query on that search engine. The results were analyzed using a paired sample t test, as reported in Table 4. The analysis revealed a significant difference between the two groups ($t=40.287$; $p<0.01$).

Results by Search Engine

A comparison was conducted for each search engine. These results are displayed in Table 5.

Table 5: Comparison of Results by Search Engine.

Search Engine	Mean of Simple Queries	Average Number of Results that Appear in Baseline	Standard Deviation	Mode	Paired sample t
Alta Vista	10	4.5	4.2	10	18.143
Excite	10	7.8	3.8	10	12.304
FAST Search	10	7.1	3.7	10	10.759
GoTo	9.93	8.4	2.8	10	7.704
Northern Light	10	5.4	3.9	10	23.433
					p < 0.01

From examining Table 5, we can see that Excite, FAST Search, and GoTo will on average return approximately seven to eight identical results, regardless of whether the query is simple or complex. The means for Alta Vista and Northern Light are lower at approximately four and five, respectively. Alta Vista has the largest standard deviation at 4.2. The modes of all five search engines were ten. The results from each search engine were analyzed using a paired sample t test, reported in Table 5. The analysis revealed a significant difference between the groups of simple and complex query results for all search engines.

Discussion of Results

The 100 original queries used for this research structurally represent the majority of Web queries that are more than one term. These 100 queries were submitted to five search engines. These queries were modified with advanced searching operators and also were submitted to the same five search engines. Approximately 66% of the results were identical regardless of how the searcher entered the query. Referring to the data displayed in Table 4, a paired sample t-test ($t= 40.287$, $p<0.01$) shows that the results from the simple queries are significantly different from the results for complex queries. However, as with all tests of statistical significance, one must ask what different does this make in the 'real world'?

Does it make sense to learn and utilize the more complex searching operators if on average it is only going to present the searcher with about three or four results that are different from those retrieved by just entering the query terms? Are the three or four different results worth the increased probability of entering a complex query incorrectly? As the complexity of queries increases, so does the probability of error.

The findings of this research suggest that the use of complex queries is generally not worth the trouble for the typical Web searcher (i.e., who uses two terms and is interested only in the first ten results). Based on their conduct, it appears that most Web searchers do not think it is worth the trouble either. One can say that the behavior of Web searchers adheres to the principle of least effort (Zipf, 1948), which postulates that there are "useful" behaviors that are quick and easy to perform. The very existence of these quick, easy behaviors causes individuals to choose them, even when they may not necessarily be the best behavior from a functional point of view. However, these useful behaviors are good enough, and people will generally expend the least amount of effort to achieve what they want. Zipf's theory can explain the behavior of Web searchers. The results obtained from Web search engines via simple queries are good enough. In IR jargon, the precision of simple Web queries meets the information needs of most Web searchers.

The use of simple queries versus complex queries is also compelling when one compares the modes presented in Table 4. The modes for the simple and the complex queries are both 10, meaning that more than any other occurrence, the results from a simple and complex queries will be the same.

Naturally, we acknowledge that there are cases where one is interested in all possibly relevant results. In these cases, the three or so new results may be worthwhile. Even in these cases, it would make sense to enter the simple query as well as the complex queries. Nevertheless, this type of information need, where one is interested in recall as well as precision, does not appear to be the typical information need for Web searchers. Not only are Web queries short and simple and the number of results viewed small, but the session length (the number of queries submitted during a session) of the typical Web searcher is one or two queries (Jansen and Pooch, 2000), reinforcing the notion that Web searching is a precision-based service. By their characteristics, the typical Web search does not represent a recall-based information need.

In reviewing the analysis by search engine, outlined in Table 5, there was a great deal of overlap between query results for most search engines, ranging from 45% for Alta Vista to 84% for GoTo. The mode for all five search engines was ten. Studies and presentations show that the failure rates among Web searchers using advanced syntax are high (Jansen et al., 2000). Why give searchers the opportunity to make mistakes? This rule seems to be the tactic followed by FAST Search and GoTo, which both limit the searcher's options. It also appears to be the tactic pursued by Excite where at least 78% of the results are identical, regardless of the present or absence of advanced searching operators.

These results would seem to indicate that system designers have developed the Web search engines so as to minimize the need to utilize advanced searching operators. Web searchers seldom utilize advance searching techniques, so designing IR systems to account for this characteristic seems like a reasonable course of action.

Concerning the lower mean of Alta Vista (4.5), it appears that this search engine uses a different ranking algorithm when the must appear operator (+) is used. Based on the rather random results retrieved with this operator, Alta Vista may adhere to the theoretical model of no ranking feature when Boolean-like operators are used in a query.

Conclusions and Future Research

This research indicates that use of complex queries appears to have a moderate impact on the results retrieved. On average, approximately 66% of the top ten results will be the same, regardless of how the query is entered. The approximately three or four different results on average may not be worth the increased effort required to learn the advanced searching rules or the increased risk of making a mistake. One can say that the typical Web searcher is adhering to a reasonable course of action by entering simple queries when using Web search engines.

These results also indicate that Web search engine designers are doing a proper job of designing Web interfaces and ranking algorithms. Given that the typical web searcher seldom uses advanced operators, web search engines are to be compensating for the naïve the searching characteristics of their customers. Based on the results of this research, one can conjecture that the ranking algorithms of these search engines adhere, albeit loosely, to the following rule: *Place those documents that contain all the query terms and that have all the query terms near each other at the top of the results list.* Naturally, this is an over simplification of the complexity of searching and ranking algorithms. However, a ranking rule like this, the use of or lack of use of advanced search operators would have little impact on the results at the top of the list.

There are several avenues for future investigation. One would be to examine the effect of longer queries. The research from this study focused on the dominant behavior of Web searchers, short queries (generally about two to four terms) and viewing ten or fewer documents. It would be interesting to see if these same results hold as the query length increases. The present study would indicate that the results would not hold for query length, based on the observed decline in overlapping results in four-term queries relative to two-term queries. However, the impact in terms of explaining Web searching behavior would be less, addressing only about 7% of Web searching. Also, more discrimination would need to be made in what advanced searching operators to utilize. For example, one can make a case that the use of phrase searching might decline as the query length increased. It would also be interesting to see if these same results hold as the number of results viewed increased.

Returning our research questions, it appears that the increased usage of advanced searching techniques by Web searchers has only moderate effect on the results from Web search engines. Therefore, the use of these operators by Web searchers may not be that helpful. It also appears that the designers of Web search engines understand the searching patterns of their typical customers and are designing IR systems to compensating for the simple searching techniques of Web searchers.

Facing the Unknown: Distributed Project Team Guidelines

Abstract

Teams working in distributed projects go through the same stages and encounter the same problems as typical face-to-face teams. The main difference when the environment is moved to a distributed setting is that some problems become more complex, other problems become less noticeable, and some new obstacles occur. One of the main problems with distributed work is getting to know each other and build trust. But there are other, more practical issues that also need to be dealt with when you are working together at a distance. In this article we present a set of guidelines developed from research with various distributed project based courses. Our conclusions are that students are not conscious of the difficulties of distributed communication and collaboration. They need guidance in resolving and avoiding common problems.

Background

We have conducted research in three different graduate courses, on five occasions, from 1999- 2001. The courses were held at Stanford University (USA) and KTH (Sweden), and in some cases with involvement from NUS (Singapore) and TMIT (Japan). The participant have mainly been engineering students, but there were a few business students in one of the courses. The students participated in globally distributed projects and collaborated by using ICT.

The research was conducted by observing teamwork, meetings, classes, etc., by conducting focus groups and interviews with faculty, students, and other people involved with the courses, through formal written surveys, and through an analysis of student papers about lessons learned during the collaborations.

It is normally easier to work together if you are co-located and see each other face-to-face regularly. Nardi and Whittaker (in press) argue that face-to-face communication will persist not only because it provides rich information, but also because it is the surest way to establish and nurture the human relationships that underlie business relationships. The relationships are grounded in social bonding and expressions of commitment that are most easily accomplished through face-to-face communication.

Cheesman and Heilesen (1999) point out that a real life meeting is hard to replace with photos, CVs, home pages and the like. All of the examples that they give are static ways of giving information about yourself, though, and do not really give any opportunities for team members to interact. Synchronous activities that involve virtual interactions may have richer results, although they may never fully replace in-person meetings. And even if pictures and biographies do not replace face-to-face interactions, they can still be valuable for helping teammates get to know each other better.

In the case of distributed team work, in-person meetings may not be possible, due to limited budgets or time. Problems arise due to the confusions that come from not seeing, knowing, and/ or trusting distant project participants. However, with simple means it should be possible to decrease some of the most common problems and make distributed teamwork easier to handle. It is interesting to consider whether it possible to work together without meeting at all. How might a team better handle working in projects at a distance? What concerns should be addressed, and what are the most important differences and difficulties that need to be solved?

Some researchers have their doubts about whether distributed teams will ever reach the same level of collaboration as face-to-face teams, that collaboration requires collective action, and such action is unlikely in virtual teams. Knoll and Jarvenpaa conducted a study with students in distributed teams without any face-to-face interaction. They found that a majority of the teams took collective action and that distance collaboration without face-to-face meetings can not only work, but can also be very successful. It just takes some extra effort to get it started.

One of our initial research interests was to examine whether it was possible to work together in a project at a distance without meeting at all. However, all teams that were observed eventually choose to meet in person. All teams emphasized the huge improvement the face-to-face meeting had on their project work. Interestingly, none of the teams put any real effort into trying to get to know each other and make the collaboration work before meeting. Thus from this research, while we show further evidence that face-to-face meetings make distributed teamwork easier, we are not able to prove whether there are other ways to achieve the same goals.

Even though meeting face-to-face helped the teams work together, they still had problems. Many of these problems could have been solved before they met. Simply discussing the specific difficulties that accompany distributed work at the outset, would have made collaboration much easier. We therefore gathered some concrete distributed team suggestions, to help the students become more aware of the problems they might encounter, avoid some of them, and help them know how to get started in this new situation.

The problems we found might seem obvious and easily solved, but our research has shown that they are often not initially observed or understood by team participants. The interesting thing is that these problems seem to recur and were noticeable in all the teams observed. None of the problems are impossible to avoid and they are easier to overcome if considered and discussed early in a project. We therefore believe that the following suggestions can be of use for distributed teams in general.

Even if you set up norms, rules, and guidelines, it doesn't necessarily mean that you have improved the collaboration. Knoll and Jarvenpaa conducted two studies where the students in one study were explicitly told to set process rules and in the other they weren't, but the students set up norms and rules to the same extent in both studies. The studies also showed how important the setting of the rules were. "When teams did not realize they had to evolve a way of working together that was amenable to all, too much time was spent on process issues disguised as content issues." To make any guidelines useful, you have to make sure they are presented in a way that is adapted to the experience and knowledge of the participants. There should also be some follow-up after presenting the guidelines to ensure they are understood and applied throughout the project. In our research, we found that students often were so immersed in details of project content, that organizational and process concerns were neglected. We propose the following guidelines to enhance virtual team collaboration.

Guidelines for Distributed Project Teams

Synchronize the Teams

Distributed team members coming from different universities probably have different schedules, requirements, and deadlines that will affect the team work. When you are working, make sure the other members of your team know what you are planning on doing, when your holidays are, your local course deadlines (if you are not part of the same course), etc., so fewer misunderstandings will occur. It is important to try to synchronize the work as much as possible, but if you can't do that, you will at least know why. Particularly, if there are multiple faculty and/ or courses involved, the faculty should, as a first step, try to synchronize the courses and their objectives. Faculty should then inform everybody involved about the differences that still exist. The students should also synchronize their particular activities.

Choose Technology That Works

Use the most stable technology possible for communication with your distributed teammates. If the technology is experimental, always have a backup plan. This is especially important if you are in a synchronous situation, like video conferencing. Make sure you have the phone number of a contact person that is usable during the time of the conference. Establish who will be reachable over email (and at what address) during the meeting. Be on time (so it is clear whether you don't have communication because of failing technology or because people are late) and set a time (e.g. 15 minutes after the conference start time) to give up or start using some other technology.

Choose the Right Technology for the Right Activity

Think about when to use what kind of media. For example, email may not be the best medium for decision-making, since it is slow and asynchronous. Email may be useful for file-sharing, updates, (light-weight) discussion, personal information, questions, planning, and briefings. Video or telephone conferences may be useful for decision making, clarifications, confirming email discussions, updates, allocations of work, and planning. These examples may or may not hold true for your team. As a team you should discuss when you will use chat, file sharing systems, web forum, telephone, videoconferencing, email, etc., and for what activities.

Discuss Norms and Rules for Behavior and Communication

You can expect that there will be conflicts, sooner or later, in your collaboration. By discussing how to deal with the problems before they actually occur, you can avoid a lot of conflicts, and establish ways to address those that do arise. You might state norms, or informally discuss expectations for behavior. This is important regarding the content of the communication, handling for example gender, personality types, cultural issues, humor, etc. Knoll and Jarvenpaa mentioned that the need to structure and making things clear is important in all teams, but absolutely necessary in a distributed team, since students don't see what their teammates are doing and can't solve the problems as they come up.

It is also important to decide how to use the different media. For example how late you can call, how and in what formats you should send files, and how many emails you can send per day without creating information overload or flooded mailboxes. You might also consider rotating roles for group meetings, such as facilitator, agenda planner, recorder, etc. This works well also because it spreads the responsibility throughout the team, which makes everybody feel more involved. Rotating roles also keeps one talkative person from monopolizing the conversation. Also try to avoid slang and talking too fast if you have non-native speaking members in your team.

Discuss and Carefully Plan any Face-to-Face Visits

Before you get to see each other face-to-face, you should discuss what the purposes are for the meeting and what you should have done by the time of the meeting, to get the most out of it. If you meet early in the collaboration you have the advantage of getting to know each other faster and therefore have the possibility to get more out of the collaboration at an early stage. If you wait until you have done some background reading, have suggestions of possible approaches or solutions, and know more what you are talking about, you have a higher chance to get more out of the collaboration in the face-to-face meeting, and you will make a better impression. The fact that the participants normally get motivation and energy out of a site visit should also be considered when you decide if you should have a face-to-face visit, and, if so, the time and place for the meeting.

Have Team Building and Social Activities

For the collaboration to be as smooth as possible, it will help if you get to know each other as well as possible. This will help you know what to expect from the other members of the team, to learn about special skills of different team members, and to be able to have fun working together. It is advisable to have some form of personal presentation in the beginning of the collaboration. This can be done for example by making a short video about yourself, your team and your campus; by making a web page where you introduce yourself; and/ or by presenting each other at a video conference. Remember- a picture is worth a 1000 words, so try to use pictures in your presentations.

Duarte and Snyder point out that when you are planning teambuilding activities, it is important to take into consideration that it might be subject to cultural bias. Experienced virtual team members might think of the activities as a waste of time. This only makes it even more important to think about choosing the right activity for the specific participants, environment, and project, and also to use the right activity in the right phase of the team development.

Think Proactively!

When you come to, especially the first, telephone or video conference, make sure you know what you want to get out of it. Make a list of what topics you want to cover, things that are uncertain and need to be clarified. Ask your distance teammates what they want to discuss and tell them what you want to get out of the meeting, so you can come to a mutual agreement. If possible, this should be shared before the meeting. Also remember, when you first start meeting, you can set the tone, and even if you have to remember that cultural and personality differences also play a big role in deciding how people will prefer communicating, being relaxed and positive yourself will help creating a good atmosphere.

Conclusions

Students working in distributed projects are facing challenges and problems they might not have encountered before, but the knowledge they can get out of this kind of work will be useful working in any line of business where you have work with or encounter other people. Just putting students in teams together with participants from different universities and countries without giving them any motivation or guidelines for the collaboration, will not give them the full advantage of the experience. Project work is in a lot of ways opportunity learning and without giving the students guidance to go in the right direction, the opportunities might only appear as problems, and the students will never get or feel the full advantage of the collaboration.

Our conclusions are that most students are not conscious of the difficulties of distributed communication and collaboration. They need guidance in resolving and avoiding common problems. Handing out simple guidelines and concrete suggestions can help the students avoid some of the worst pitfalls and put them on the right track earlier, and a small effort and careful thought can make a collaboration successful. The guidelines you find in this article point to problems that have recurred in all classes observed, and they provide a simple method to start helping distributed students get a better work situation and improve their learning situation.

It is important to synchronize members and sub-groups of a team as much as possible. For student teams, initial synchronization should be arranged by the faculty. The faculty should help the students continue to synchronize as the project proceeds. The choice of technology is very important when you are working at a distance, since most of the communication will be conducted via technology. Choose technology that works and is easy to use. It is important to choose the right technology for every specific activity. Discuss how you should use the different media and how to behave in different situations when using it. Since there are fewer natural ways of socializing when at a distance, make sure to have teambuilding and trust building activities. Discuss if, when, and why you should meet face-to-face. One of the most important things to create a good working and learning environment is to be proactive and work for the changes you want to see. Working at a distance can be very rewarding, but only in the context of active and thoughtful organization and synchronization of team activities.

Future work

Future research on distributed teams should explore methods for minimizing the need for meeting face-to-face. One method could be to compare teams that meet, with those that don't meet at all (but have a strategic plan for how to build trust and get to know each other at a distance). Such analysis could help both completely distributed teams, but also help teams that will meet occasionally, to get a better start. This would make it possible to observe what improvements teams have (if any) after discussing guidelines for behavior and distributed work, having teambuilding activities, etc.

New Trends in Web Usage Patterns and Web Traffic

Abstract: As the Web is expanding, the Web traffic is changing, and so are the users. To get an adequate understanding of the Web as a medium, it is of paramount importance to know the users and the dominant usage patterns. The purpose of this paper is to map important aspects of Web usage patterns, Web traffic and Web search behavior. Issues dealt with are, among other things, time spent per month, number of sessions per month, time spent during surfing session, page viewed per session and per month, duration of page viewed, number of unique sites visited, concentration of and the recent developments in Web traffic, given sites' shares of total page views, and significant aspects of Web users search behavior (e.g., frequency, time spent searching, kind of information search for, most popular search terms, satisfaction etc.).

[If you read this file from the screen, please choose the 'Page Layout'-option in the View-menu to view the figures and charts. The final version of the paper will include updated figures and graphs for the year 2002.]

In the paper "Mapping the Web. A Media Typology for Information Traffic Patterns on the Internet Highway" (Jensen, 1996) I delineated a basic typology for information traffic patterns and media types on the Internet; in the paper "WWW - Who? Where? Why?" I outlined a media sociological analysis of demographics, consumer trends and content trends on the Web (Jensen, 2000a); and in "Trends in interactive Content & Services on the Web" (Jensen, 2000b) I summarized seven major new trends concerning content and services on the Web. In the context of this paper, I want to proceed with this line of action and sketch a number of new trends in Web usage patterns, Web traffic and users search behavior.

The Internet is growing fast. According to Inktomi there are now more than one billion unique documents on the Internet. The total number of servers is well over 6 million. And the total number of users surpassed the 400 million mark in 2000 and will continue to grow exponentially in the years to come. As the Internet and the Web are expanding, the content is changing too, and so are the users. To achieve an adequate understanding of the Web as a medium, it is of paramount importance to know the users and to understand the dominant Web usage pattern.

The purpose of this paper is to track changes in the Internet: to map Web usage patterns and Web traffic, thereby establishing an understanding of the new Web user. Due to limited space, among other things, this study will focus only on three aspects:

- Web Usage Patterns
- Web Traffic
- Web Search Behavior

Web Usage Patterns

Figures on average Web usage from Nielsen//NetRating from the last couple of years show that the total time spent per month on the Web has gone down lately and that it seems to stabilize around 10 hours per month. At the same time the number of pages viewed in a month and the number of page views in a session is going up. Consequently, the duration of a page viewed is going down.

Table 1 shows the growth in time spent per month over the last year and a half. From 7:34:28 (hr:min:sec) in July 1999, 9:26:51 in January 2000, to a height of 10:04:05 in October 2000, the time spent per month has now fallen to 9:37:25 (February 2001). Thus, it seems as if the time spent per month on the Net has stabilized just below 10 hours per month.

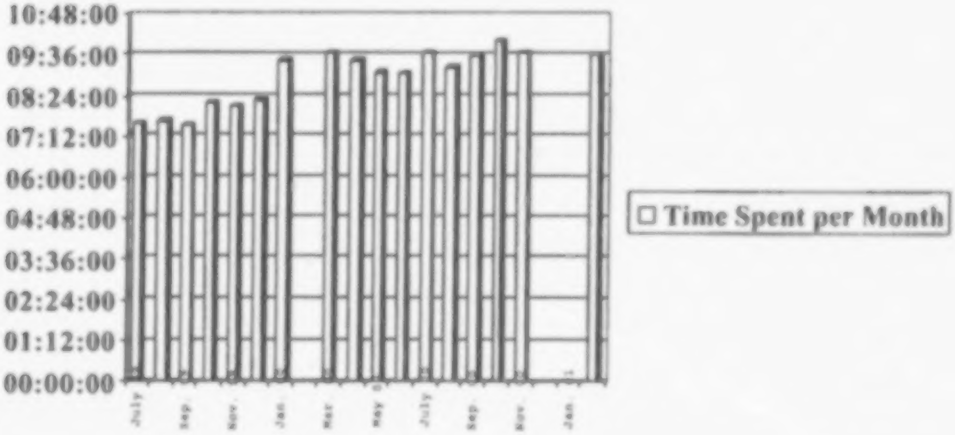

Figure 1: Time Spent per Month [Nielsen//NetRatings 1999, 2000, 2001, The reported Internet Usage estimates are based on a sample of households that have access to the Internet and use platforms such as Windows 95/98/NT and MacOS8 or higher]

Likewise, the figures estimate that the number of sessions per month is down to 18. From an average of 16-17 sessions per month in 1999, and an average of 18-19 sessions per month in 2000, the number seems to have stabilized around 18 sessions per month in the recent period (cf. Table 2).

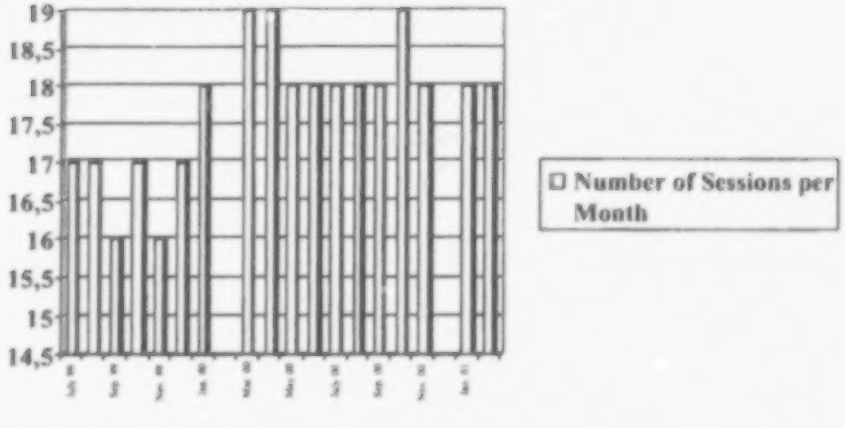

Figure 2: Number of Sessions per Month

The average time spent during a surfing sessions has been steadily increasing from 26:44 (min:sec) in July 1999 to 32:22 in February 2001. However, over the last year or so, the figures have been rather stable.

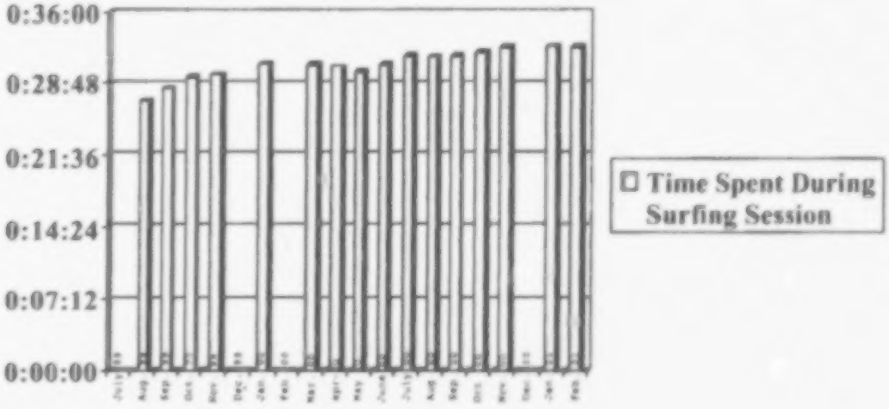

Figure 3: Time Spent During Surfing Session

Figures, which seem to be constantly increasing, concern the number of pages viewed per session and the number of pages viewed per month. Concerning the number of pages viewed per session, it has gone up from 20 pages in July 1999 to a height at 41 pages in August 2000, falling again to 38 in the fall of 2000. (It has not within the deadline of this preliminary paper been possible to get the data from Q4, 2000 and

Q1, 2001. They will, however, including the new data from Q2 and Q3, 2001, appear in the final version of the paper.)

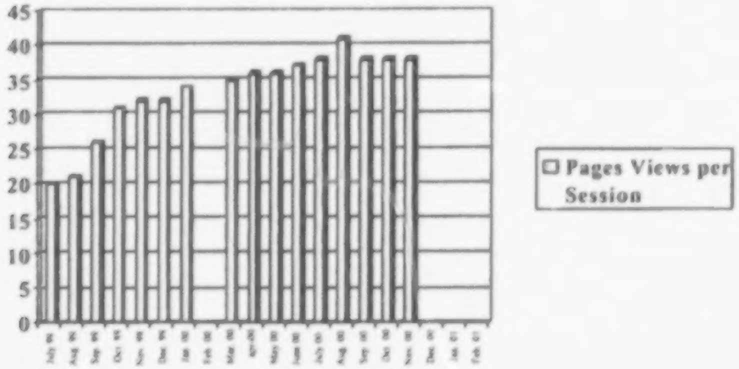

Figure 4: Pages Views per Session

Correspondingly, concerning the number of pages viewed per month, it has grown from 332 in July 1999 to 720 in October 2000 and 689 in September 2000. Thus, the number of pages viewed per month has more than doubled in a year. (It has not within the deadline of this preliminary paper been possible to get the data from Q4, 2000 and Q1, 2001. They will, however, including the new data from Q2 and Q3, 2001, appear in the final version of the paper for the proceedings.)

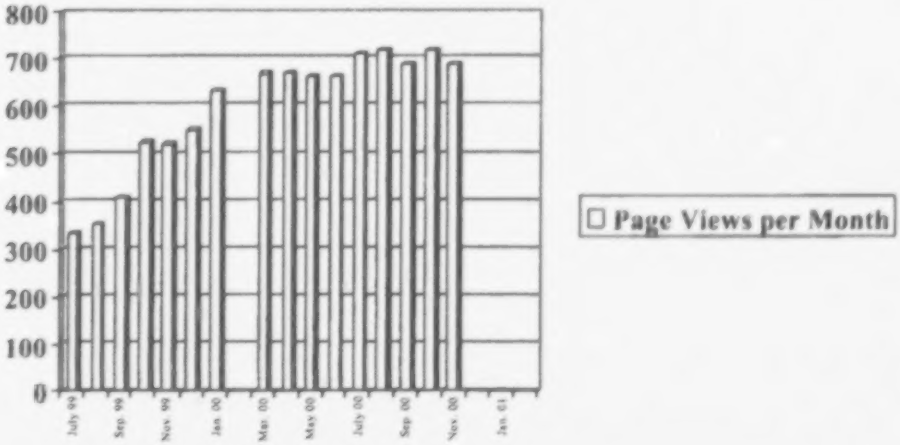

Figure 5: Page Views per Month

Following from the above, the duration of a page viewed has gone down. From an average of 1 minute and 20 seconds per page in July 1999 the duration has now stabilized around 50 seconds (February 2001).

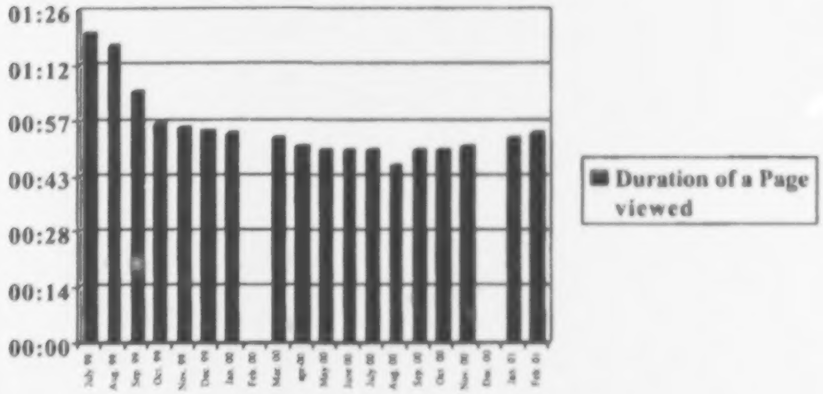

Figure 6: Duration of a Page Viewed

The average number of unique sites visited in a month is down to 10 and this figure seems to be one of the most constant. While the number of unique sites visited was around 12 in July-August 1999 it has been fixed on 10 sites the last year or so. This indicates that irrespective of how many sites there are on the Web, users tend to find their favorites and stick with them. That is, users are beginning to show loyalty to a limited number of sites: The Internet surfers are turning into Internet settlers. Each user has preferences for and loyalty to Web sites they visit.

Coincidentally, this number of unique sites visited is comparable to the number of channels actually viewed in a TV household. While the number of channels and viewing options available in the average TV home continues to grow, the number of channels actually viewed in the average household has not grown beyond 13 (Nielsen Media Research 1999).

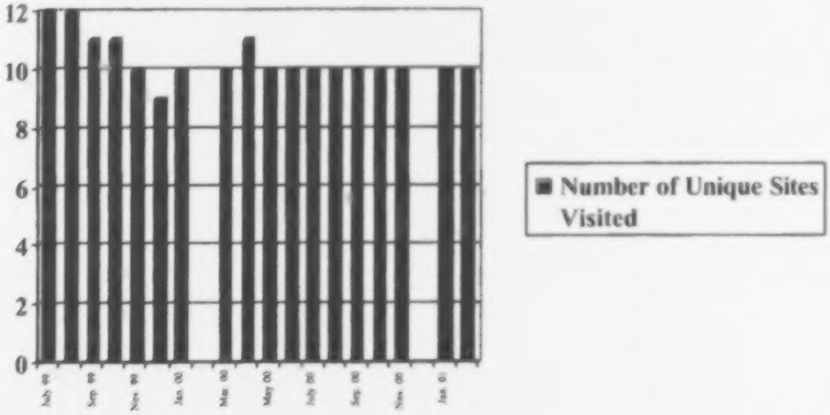

Figure 7: Number of Unique Sites Visited

Web Traffic

Although the Web is enormous there is still a significant concentration as regards content and Web traffic. In 1999, OCLE Research reported that the largest 25.000 sites represented 50 percent of all available content on the Web. Likewise, in 2000 Netcraft reported that 80 percent of all traffic on the Web ends up at only 0,5 percent of all URLs, corresponding to approximately 15.000 URLs.

Although Web traffic, as these figures indicate, is highly concentrated, a new survey by Alexa Research reports that the Web has become more dispersed in the past seven months. Based on a comparison of Web traffic in June 2000 contra January 2001, the study shows

- that the top 10 sites accounted for 11 percent fewer page views in January 2001 than they did in June 2000, i.e., the Web was 11% less concentrated in January compared to June
- that the top 100 sites accounted for 12.2 percent fewer page views in January 2001 than they did in June 2000, i.e., the Web was 12.2% less concentrated in January than it was in June
- and that the top 1000 sites accounted for 9.4 percent fewer page views in January 2001 than they did in June 2000, i.e., the Web was 9.4% less concentrated in January as compared to June

Looked at from another perspective, we could say that, in January 2001,

- 1 in 6 (16.6%) page views occurred at one of the top 10 sites
- nearly 3 in 10 (29.6%) pages was viewed at one of the top 100 sites
- and nearly half (48.3%) of all pages viewed on the Web was viewed at one of the top 1,000 sites.

All the above-mentioned figures are down from June, designating a less concentrated distribution of page views across the Web (cf. Table 1).

The Top...	**% of all page views in June 2000**	**% of all page views in January 2001**	**% dilution b/w June & Jan.**
10 sites	18.6 %	16.6 %	11.0 %
100 sites	33.7 %	29.6 %	12.2 %
1000 sites	53.3 %	48.3 %	9.4 %
accounted for			

Table 1: Top Sites Percentage of all Page Views

Thus, the top sites' share of overall Web traffic is being watered-down. In this way the Web is becoming more distributed, more equalized and balanced, and perhaps even more democratic. And yet, the majority of all Web traffic is still ending up on a very small part of the millions of sites on the Web.

BEST COPY AVAILABLE

An alternative way of indicating the reduced concentration of Web traffic is to contrast the number of sites that accounted for a certain share of the total page views in June and January (cf. Table 2)

Of the total pages viewed on the Web ...	**Number of Sites in June 2000**	**Number of Sites in January 2001**	**% Change in No. of Sites**
1 in 5	13	21	61.5 %
1 in 4	27	50	85.2 %
1 in 3	95	169	77.9 %
1 in 2	695	1,210	74.1 %
occurred at the top			

Table 2: The Number of Sites that Accounted for a Given Share of Total Page Views in June Versus January

This means that, in June 2000, 13 sites accounted for 1 of every 5 pages viewed on the Web. In January 2001, that number grew to 21, which means an additional 8 sites or 61.5% more sites shared that fifth of the web. Likewise, in June 2000, 27 sites represented 1 of every 4 page views, whereas that number was up to 50 in January 2001, meaning that 85.2% more sites sha red that forth of the web. Finally, in June 2000, 695 sites accounted for half of all Web traffic, whereas in January 2001, 1,210 sites shared that half, signifying that 74.1 % more sites shared half of the Web.

A final indication of the more dispersed Web traffic is that a larger collection of sites is showing high counts of visitors. Whereas only four sites had more than one billion page views in June 2000, that number had grown to 17 sites in January 2001.

However, despite this decreasing concentration of Web traffic, the leading sites are still attracting the lion's share of all page views.

Conclusions

This study shows, among other things,

- that the Web is changing and so are the Web traffic and Web usage patterns
- that the total time spend per month on the Web is going down but, at the same time, that the number of pages viewed in a month and the number of pages viewed in a session is going up, and, consequently, that the duration of a page viewed is going down
- that the number of unique sites visitedin a month is down to 10 and this figure seems to be relatively constant
- and that Web traffic is highly concentrated, but that the Web has become more dispersed in the past months.

Virtual Reality: The Future Of Animated Virtual Instructor, The Technology and Its Emergence To A Productive E-Learning Environment

Juhanita Jiman
Center for Interpretation and Expression,
Faculty of Creative Multimedia, Multimedia University
Cyberjaya, MALAYSIA
juhanita@mmu.edu.my

Abstract: The promise of Virtual Reality (VR) has caught our imagination and reliable networks will make it all a reality. VR will draw from and affect the entire spectrum of culture, science, and commerce, entertainment, and education industry. It will be multi-national, and will introduce new hybrids of experience for which descriptors presently merely exist.

In this paper, my major discussion will be the use of VR in e-learning environment where an intelligent 3D virtual person will play a role of an instructor. With the existence of this virtual instructor, it is hoped that the teaching and learning in the e-environment will be more effective and productive. This virtual 3D animated character can actually be programmed to have a natural human touch to help breaching the gap between a machine and student. A virtual instructor that has an almost true look and feel of a human being will make the students feel more comfortable and confident to learn.

Keywords: E-learning, Virtual Instructor, Intelligent Agent, Character Animation, Virtual Reality, Avatar, Collaborative Learning, Artificial Intelligence, Facial Expression.

Introduction

There are as many definitions as there are applications of "virtual reality". For most people, this technology is more seen like something magical, with endless possibilities. The best definition would be: "Virtual Reality is a way for humans to visualise, manipulate and interact with computers and extremely complex data. It is supported by advances in simulation technology that allow linking human capabilities and computational resources, sensor systems and robotics devices for real-time tasks." This was taken from the book "Silicon Mirage: The Art and Science of Virtual Reality". [1]

We foresee that computing environments in the near future will be very widely distributed and mutually connected. New services will be added from time to time, while old services will be replaced. Network topology and capacity will be changing almost continually. Users will demand much better user interfaces, so that they will be able to communicate with computers as if they are communicating with humans. VR technology can be applied to many tasks that would be more difficult to do by other methods. With VR technology, a human and a computer operate together as a combined system, one that is far more capable than either taken individually when performing a large variety of tasks. It offers a multitude of ways to improve productivity. VR will not serve only to create hit video games or other applications of that sort, but, more importantly, this technology is put towards more functional applications.

In education, VR would allow collaborative and distance learning to occur more successfully and make students to travel to places that may not be feasible otherwise. They could do scientific experiments in a simulation even though they could not afford to do the real experiment because of the cost of the equipment. Furthermore, in the educational domain, VR without any doubts has played an important role to assist teaching. There has long been a philosophical gap between distance education and efficient training skills, and because of these difficult tasks, VR has increasingly become an important teaching aid. With the emergence of this technology, education and training are now getting their feasible and better solution. Education's goal which has traditionally been to impart high-level cognitive skills that would tie a lifelong learning process and training's goal which was to bring performance up to a skill level that would let people successfully carry out new tasks can now be improved with the help of VR solutions.

Content

LEARNING WITHOUT LIMIT

Collaborative Learning and Virtual Reality Learning Environment

Collaborative Learning in VR provides an environment to enlighten and enrich students' learning process. This will be a better place where they could benefit it the most without having to go to a real classroom or a training place. Introducing interactive virtual instructor or partners into an educational system creates more realistic social contexts, thereby it will increase the effectiveness of the learning system. This almost 'true human' virtual learning environment would definitely help sustain the student's interests and would provide a more natural learning habitat.

As Piaget [2][3], pointed out, collaborative learning has a major role in constructive cognitive development. His theory is consistent with the other popular learning theory [4] in emphasising the importance of collaboration. Piaget felt that interaction between peers has to be equally shared in a collaborative environment to maintain performance.

In one-to-one computer-based tutoring, the system interacts with one student and attempts to personalise the tutoring to the needs of the student. On the other hand, in a one-to-many collaborative learning environment, the system interacts with a group of students, imparting the subject knowledge using a collaborative learning strategy. It should be distinguished that a one-to-N environment is not a combination of many one-to-one learning environments. Collaborative learning presents an environment in which a student interacts with one or more collaborating peers to solve a given problem. The interactions among the students are monitored and controlled by a collaborative learning system and in this case this monitoring or mentoring system will likely doing its best if it is supervised by an animated character as a virtual instructor.

In general, collaborative learning is found effective in domains where peers are engaged in skill acquisition, joint planning, categorisation, and memory tasks. The idea is that peers learn the prerequisites of the topic to be learned and reinforce the topic using the collaborative environment. There have been a number of studies that proposed collaborative learning to help learners understand complex tasks. For example, Miyake[5] shows that the complex understandings of the working of a tailoring machine is better understood when the peers interacted collaboratively and attempted to understand the problem. Connah et al. [6] believe that the co-operative behaviour supports higher cognitive learning, based on a simulated physical world domain.

LEARNING WITH ASSISTANCE

The Needs for Virtual Instructor

In a traditional classroom, out-spoken and active students can easily dominate class discussion. Even a skilful educator should learn how to cut this off without alienating the over-talker, but time is still lost in the process. In the asynchronous online course, with the existence of a virtual facilitator, each participant is given equal time for participation. Verbose response can be skimmed or ignored. In addition, students can benefit equal information sharing and the learning environment will somehow becomes more productive.

It is obvious that in any e-learning environment, the instant availability of a human tutor would be the most ideal way to help out if there's any complications occur involving the course materials, however, providing this capability is no more realistic than continuously providing a human tutor for the traditional classroom-based learning experience. Cost and availability are limiting factors in supplying continuously attentive human tutors. Often students simply want questions answered and would be happy with any type of effective immediate feedback, it does not matter whether it comes from a human or machine. It is still under intensive research to 'create' an avatar as an intelligent agent who is capable to give any type of on-demand feedback for certain types of information requirements.

In most cases of e-learning delivery systems, a virtual instructor is foreseen to play an important role to enhance the overall e-learning activity. It is hoped that in the nearest future, an 'almost human' virtual instructor would help the advancement of e-learning technology. An intelligent agent here, is a 'programmed' character which is considered by e-learning user as an assistant or facilitator. This agent does not function as a tool that is normally use in a conventional direct-manipulation interface, but, it serves the user with a more personal assistance. This agent should be able to illustrate characteristics that are associated with human intelligence: learning, judgement, adaptability, independence, creativity, emotion, etc.

While students are in the e-learning environments, there are risks of losing cohesiveness and spontaneity of the classroom experience, therefore, it is essential to understand how to improve the e-learning experience, and hopefully this virtual 'facilitator' will even exceed traditional teaching and learning methods.

Virtual Reality Learning Environment

Virtual reality simulation environments can also be part of e-learning delivery method which offers exciting opportunities and challenges for intelligent tutoring systems. Students, immersed in a 3D computer simulation of their work environment, improve their skills through practice on realistic tasks. Computer tutors can inhabit the virtual world along with students, allowing them to physically collaborate with students on tasks, and they can interact and communicate in non-verbal or verbal communication.

The research reported for ALN courses stated that electronic or computer based learning can be improved by the introduction of autonomous intelligent software agents. This finding has been shown in several ALN (Asynchronous Learning Networks) venues [7], [8]. Intelligent Agents (IAs), can perform the duties of online facilitators for routine tasks. Checking computer code, responding to simple questions, reminding learners about the need to turn in assignments and potentially even grading essays [9] are among the types of things that intelligent agents can accomplish.

With this advent of intelligent agents, it enables learners to be trained, manipulate and work within the 3D virtual world, which finally led to the interactive learning systems of the new millennium.

Animated Virtual Instructor that Has Intelligence

In the midst of needing a mentor in e-learning environment, it comes to attention that a virtual instructor would be the answer to all the woes. This virtual instructor would be in a form of animated human being. This animated agent will play a role of a *'Virtual Instructor'*.

This *'Virtual Instructor'* as an intelligent agent is programmed to have a natural human touch to help breaching the gap between a lifeless machine and the student. As a character that has an almost true look and feel of a human being, this agent will make the students feel more comfortable and confident to learn. While students are interacting to this agent, they will experience a sense of equality. Nervous or slow students will feel more comfortable in any of the learning activities and feel more secure when communicating with this virtual person instead of speaking in an actual training place. As a whole, this agent is programmed to be more accessible, patient, understanding and most of all efficient in all aspects.

Getting the right information is crucial for the emotional process and for this agent to generate an accurate or desirable answer. Therefore, this agent is designed to have abilities to 'learn' and later to track the history of events that have happened, then, link it to the most likely solution.

Desirable Qualities of 3D Character as an Intelligent (Software) Agent

Etzioni and Weld defined the term "software agent" as a computer program that behaves in a manner analogous to a human agent [10]. In essence, the term refers to software that supports a social interface metaphor, a dialogue between a person and the agent. Various researchers proposed the following characteristics as desirable qualities of software agents :

- Autonomy: An agent initiates and exercises control over its own actions in the following ways:
    - Goal-oriented: accepts high-level requests indicating what a human wants and responsible to decide how and when to satisfy the requests.
    - Collaborative: does not blindly obey commands but can modify requests, ask clarification questions, or even refuse to satisfy certain requests.
    - Flexible: actions are not scripted; the agent is able to dynamically choose which actions to invoke, and in what sequence to do the action.
    - Response to the state of its external environment.
    - Self-starting: unlike standard programs directly invoked by the user, an agent can sense changes in its environment and decide when to act.
- Temporal continuity: An agent is a continuously running process, not a one-shot computation that maps a single input to a single output and then terminates.
- Personality: An agent has a well-defined believable personality that facilitates interaction with human users.

- Communication ability: An agent can engage in complex communication with other agents, including people, to obtain information or enlist help to accomplish its goals.
- Adaptability: An agent automatically customises itself to the preferences of its user on the basis of previous experience. It also automatically adapts to changes in its environment.
- Mobility: An agent can transport itself from one machine to another and across different system architectures and platforms.

Virtual Instructor in VR Learning/Training Environment (Farieda)

- ***Farieda in General***

As it was said earlier, virtual reality can be used for any training needs, from linguistics, mathematics, sciences, computer skills, engineering and many others. To master complex tasks in different kinds of training, students definitely need hands-on experience and they have to face a wide range of situations. They also need a mentor/instructor that can demonstrate procedures, answer questions, and monitor their performance, while on the other hand, they may also need other students' participation (team-mates) if their task requires multiple people.[11] It was hypothesised that face-to-face professor-student interaction is crucial to test performance. However, the data indicate the reverse, that virtual interaction produces better results. [12]

Medicine will probably be the most commonly known area that VR is used for training, but, apparently, it is not the only area that can utilise VR in its applications. There are also many branches of other scientific and non-scientific fields to adopt virtual reality for diverse applications. In other words, it means that this enabling technology can be used to improve productivity in many important areas. There are numerous applications in the domains of health care, education and lifelong learning, manufacturing and other areas where this technology shows great promise.

In the midst of needing a mentor in collaborative VR learning environment, it comes to attention that a virtual instructor would be the answer to all these problems. This virtual instructor would be in a form of an animated human being and it will play a role of an 'intelligent instructor'. The agent is given a name as Farieda (Friendly And Reliable, Intelligent E-Learning Development Agent). Farieda integrates methods from four primary research areas: intelligent tutoring systems, computer graphics, agent architectures and speech recognition. This novel combination results in a unique set of capabilities.

Farieda is programmed to have a natural human touch to make the communication between a machine and student to occur more successfully. As a virtual instructor that has an almost true look and feel of a human being, she will make the students feel more comfortable and confident to learn. While students are interacting to Farieda, they will as if that they are interacting with a natural human tutor. In addition, nervous or slow students will feel more comfortable in this training because they will feel more secure when communicating with this virtual person instead of speaking in an actual training place. As a whole, Farieda is programmed to be more accessible, patient, understanding and efficient in all tasks given to her as a 'tutor or facilitator'.

- ***Farieda Architecture and Capabilities***

Farieda's artificial intelligence is designed to allow more human-like interactions among synthetic agents and humans. Her speech recognition makes her appeared to be more human than other virtual instructor. Farieda's architectural capabilities on the other hand, allows her to energetically handle a dynamic virtual world, where this becomes a place where people and other agents meet. She will continually monitor the state of the virtual world, always maintaining a plan for completing her current task, and revising the plan to handle any unexpected situations.

Getting the right information is crucial for the emotional process and for this agent to generate an accurate or desirable answer. Therefore, Farieda is designed to have abilities to 'learn' and later to track the history of events that have happened, then, link it to the most likely solution. She has many instructional capabilities one would expect of an intelligent tutoring system. For example, she can answer questions such as: "***What should I do next?***" and "***Why?***". On the other extreme, by using her voice recognition capabilities, she can also give responses if she's sensing that the student is not paying attention or confused, she will say ***"Are you ok there? Why are you keeping quiet?"*** or if she's sensing that the students are having fun, she will say ***"That's enough let's go back to our topic!"***. Moreover, because she has an animated body, and cohabits the virtual world with students, she can provide more human-like assistance than the disembodied tutors. For example, she can demonstrate actions, use gaze and gestures to direct the student's attention, and guide the student around the virtual world.

More importantly, Farieda is designed and programmed to have a set of domain-independent capabilities that utilise a declarative representation of domain knowledge. To teach students about the tasks in a new domain, Farieda will be

BEST COPY AVAILABLE

programmed with the appropriate domain knowledge in detail and she has to 'know by hard' whatever topic or content that is relevant to what she is going to teach. It is assumed that Farieda will be a course author, a person with enough domain knowledge to create a course for teaching others. Importantly, people should not aware that Farieda has any programming skills or being programmed, ensuring that Farieda only relies on types of knowledge that a course author can provide imposes strong constraints on Farieda's design. Farieda is designed to coexist with other people and agents in a virtual world. Her goal is to support team training and collaborative learning, where teams of people, possibly at different locations, can inhabit the same virtual world and learn to perform tasks as a team.

- ***Farieda's Gesture, Look and Feel***

As a virtual instructor who has to have a look and feel like a natural human beings, Farieda is modelled with a detail human character and her gesture is more or less have to reflect on what natural human is capable of doing. Farieda will not only show a set of different facial expressions to show her so-called 'emotion', her body movement or gesture will also be an important part in her existence.

As an intelligent agent, Farieda is supposed to be sensitive towards her virtual collaborative learning environment. For example, if Farieda is sensing that one of her students or trainees is not paying attention, she will show that she cares by giving a positive comments and ask the student to pay more attention, but if repeatedly the same student is doing the same thing and this is distracting other students who are engaged in that collaborative learning, she will be more firm and has the authority to log out the destructive student.

- *Farieda's Facial Expression*

Farieda's artificial intelligence is designed to allow more human-like interactions among synthetic agents and humans. One of the particular strengths of animated characters is their ability to express emotions in a believable way by combining facial expressions with body gestures and affective speech. [13]

Farieda's personality is represented by a vector of discrete values along a number of psychological traits, such as extraversion, openness or agreeableness, that uniquely characterise an individual. These personality traits are not influenced by current events, but remain stable over a longer period of time. [14] Thus, this agent becomes more personal and individual, where it would be almost 'human' who has feeling and emotion. Within these agents' believable human 'personality', they can give comments within their domain knowledge, show dedication through their friendly approach, show their sensitivity through voice intonation (if not happy the intonation would be higher and vice versa), able to make simple laugh and show appreciation but most of all they are better than human because they will never be tired, bored or incline to favouritism and discrimination.

It has come into researchers' attention that ability to express emotions is important for creating believable interactive characters. To simulate emotional expressions in an interactive environment, an intelligent agent needs both an adaptive model for generating believable responses, and a visualisation model for mapping emotions into facial expressions. [15]

Conclusion

VR enabling technology can be used to improve productivity in many important areas. There are numerous applications in the domains of health care, education and lifelong learning, manufacturing and other areas where this technology shows great promise. Early results have shown increased productivity and a dramatic reduction of resource requirements in many instances and from there the future of VR is seen more encouraging.

In many cases of VR applications, virtual training is one of the highly demanded solutions. Self-paced training is known to be responsive to every learner's needs and with the help of a virtual instructor in a form of animated 3D character, the learning process can be more interesting and effective.

Teaching and learning in a conducive environment definitely will help students/learners to benefit the most from the learning process. Optimal learning satisfaction has been proven to give a major impact on the emotional process, therefore, satisfied students will not only be motivated to learn but in a way they will be 'hooked ' and committed to their study. Guided lessons can be enriched by having "somebody" to who the learner can refer. This implies the provision of a

BEST COPY AVAILABLE

'virtual instructor'. A talk agent as a virtual instructor could replace streaming video instruction and act like a 'true' human instructor.

Even with the existence of this virtual instructor, it is still a student-centered teaching approach where the students themselves determine what their needs are. The virtual instructor's most crucial job is to accommodate different learning styles and provide them with opportunities for exploration. It is hoped that the ability of the virtual instructor to communicate with the learner will advance e-learning to a higher level.

Abstract: The rapid growth of web-based instruction has raised many questions about the quality of online courses. It appears that many online courses are simply modeled after traditional forms of instruction instead of incorporating a design that takes advantage of the unique capabilities of web-based learning environments. The authors present a conceptual framework that can guide the development of online courses. Specific examples of instructional strategies that fit the framework are described in detail.

Introduction

Distance education is an instructional delivery system that allows students to participate in an educational opportunity without being physically present in the same location as the instructor. Although print-based correspondence study is the traditional method of distance education, more contemporary approaches rely heavily on various forms of instructional technology (Garrison, 1987). The reason for much of the growth in distance education programs in recent years is due to the development of the Internet and improvement of technologies that support online learning environments. For example, among higher education institutions offering distance education, use of two-way interactive video and one-way prerecorded video was essentially the same in 1997–98 as in 1995 while the use of asynchronous Internet-based technologies nearly tripled in that same time period (Lewis, Snow, Farris, Levin, & Greene, 1999). This change is not new to the distance education community, which has seen technology-based educational innovations come and go with much fanfare. The instructional films of the 1940's were expected to radically change the educational delivery system, as were instructional radio and television. While each of these technology innovations had some impact on educational programs, they did little to change the fundamental nature of education. The Internet and computer technology, as the next generation of technological innovation to impact distance education, appears to have the power to significantly alter the education landscape.

In spite of the rapid growth of distance education, there is considerable concern about the effectiveness of this educational innovation. Numerous studies comparing traditional classroom-based instruction with technology-supported instruction have found no significant differences on critical educational variables such as learning outcomes and student satisfaction (Clarke, 1999; Johnson, Aragon, Shaik, & Palma-Rivas, 2000; Navarro & Shoemaker, 1999; Smeaton & Keogh, 1999). A popular web site (http://teleeducation.nb.ca/nosignificantdifference) contains a listing of over 300 research reports on technology for distance education (Russell, 1999). This comprehensive bibliography spans seven decades and highlights studies that found little or no significant impact of instructional technology on various educational variables.

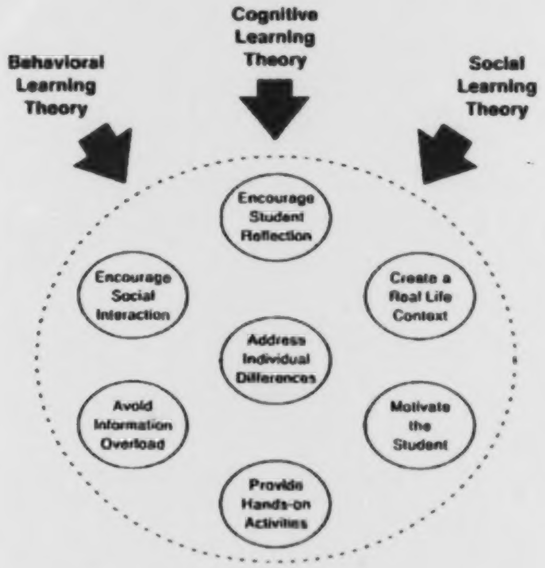
The obvious conclusion of many scholars in the field is that the technology used to support instruction has little impact on students' attainment of educational outcomes. The primary factor in any instructional initiative, irregardless of format or venue, is the quality of the instructional design that is ultimately implemented.

This paper describes a research and development effort that evolved during the creation of an HRD graduate program (*HRE Online*) that was taught entirely online. The learning environment that was created to support *HRE Online* was based on the assumption that learning is a complex event that cannot be explained with a single theory of learning. Instead, we hypothesized that quality learning environments should be based on instructional principles that are derived from multiple learning theories. Through an analysis of existing literature and experienced-based practices throughout the development of *HRE Online*, we sought to answer the following questions:

1. What instructional principles for online learning environments can be derived from a fusion of multiple theories of learning?
2. Based on those principles, what specific instructional strategies or techniques can be applied in an online learning environment?

Instructional Principles for Online Learning Environments

The pedagogical model used to develop the *HRE Online* master's degree program was created by building on specific aspects of adult learning theory (Bandura, 1971; Skinner, 1968; Thorndike, Bregman, Tilton, & Woodyard, 1928; Vygotsky, 1978). Two conceptual models that were developed from an extensive study of the literature were reviewed. These two models were then synthesized into seven general principles that appear to be critical for quality learning environments (Johnson & Thomas, 1992; Johnson, 1997). We contend that powerful online learning environments need to contain a combination of these principles: (1) address individual differences, (2) motivate the student, (3) avoid information overload, (4) create a real-life context, (5) encourage social interaction, (6) provide hands-on activities, and (7) encourage student reflection (see Figure 1). This pedagogical model for online instruction was used to create the design template that is followed for each course in the *HRE Online* program. The following section provides specific examples of instructional strategies that have been used in the *HRE Online* program. Each of these strategies highlights the importance and practical application of the seven principles of quality online learning environments.



Cognitive Learning Theory
Behavioral Learning Theory
Social Learning Theory
Encourage Student Reflection
Encourage Social Interaction
Create a Real Life Context
Address Individual Differences
Avoid Information Overload
Motivate the Student
Provide Hands-on Activities

Figure 1. An Instructional Strategy Framework for Online Learning Environments

Using the Framework to Create Instructional Strategies for Online Courses

Individual Differences

Individual differences specific to learning and instruction can be found within intelligence, cognitive controls, cognitive styles, learning styles, personality types, and prior knowledge (Jonassen & Grabowski, 1993). Each dimension helps us understand 1) patterns of thinking and reasoning about information, 2) how individuals process information to make sense of the world, 3) preferences for information processing, and 4) how past knowledge, skills, or ability influence the learning process. Each of these dimensions, collectively, helps to describe one's personality.

Recognition of individual differences has, for the most part, been taken into account and promoted through the instructional design template used in *HRE Online*. The following techniques and strategies have been used in our online courses to address individual differences.

1. *Provide content in multiple formats*. This is done through the use of various communication technologies. Lectures are audio streamed and synchronized with the applicable PowerPoint presentation. These lectures are additionally transcribed and posted in the course website. Content is also presented through WebBoard discussion groups. Each course also has links to outside web sites that provide supplemental material on the current topic.

2. *Allow for individual locus of control*. All courses provide various means of navigation within the online course. Content can be accessed through links or a graphical organizer. An individual can be as systematic or random in his or her access of course material as they desire. Although the course is built and presented in a hierarchical sequence, it does not have to be accessed in the same way. While it is not necessarily encouraged, students are also not discouraged from moving through the course in a random order.

3. *Encourage active and collaborative interaction*. Recognizing that "the whole is greater than the sum of the parts," each course is designed with activities that are both individual and group based. Working within "virtual teams," students work together to solve problems, analyze cases, and develop group deliverables. These assignments allow individual ideas, perspectives, and experiences to be heard and collectively considered.

Motivation

The ARCS Model of Motivation is a practical way for instructors to address the issue of student motivation (Kellar & Suzuki, 1988). This model breaks motivation into four major concepts; (1) Attention, (2), Relevance, (3), Confidence, and (4) Satisfaction. Instructors must be able to gain and maintain students' attention by providing an environment that is interactive and participative. While keeping the students' attention is critical, it cannot be maintained unless the students feel that the course material is relevant. Students must also feel confident that they can achieve the expected outcomes of the course; therefore instruction should be flexible to compensate for individual student needs. The final component of the ARCS Model is satisfaction, which corresponds to whether or not students derive satisfaction from the instruction.

Strategies for enhancing student motivation in a web-based environment can best be characterized as either novel and entertaining approaches or attempts to personalize the instruction. We have successfully used to following techniques to enhance the motivation of our online students.

1. *Incorporate games into the online environment*. An example of a successful game for an online course is the popular television show called "Who Wants To Be A Millionaire." We have used this game during live synchronous sessions to summarize course content covered previously and to provide a sense of community among the students. The instructor plays the role of Regis Philbin, the game show host, and reads a question that requires the students to put a sequence of answers in the correct order. The students then type the correct order (e.g., B, C, D, A) as quickly as they can into a WebBoard chat window. The student who first answers

correctly becomes the contestant who calls a toll free number so their voice can be patched through to the class. This provides live dialogue when the instructor asks a student the first of several multiple-choice questions.

2. *Simulate a radio talk show with multiple DJs and "call-in" guests*. In many online courses the students spend much of the "class time" listening to the instructor through streaming audio or video technologies or during a live "web cast" during a synchronous class session. As we all know, it can be both boring and difficult to listen to one voice for any length of time, especially when there are few visual cues to accompany the audio. To provide variety and a livelier online atmosphere, we have been successful having multiple speakers interact during these broadcasts to liven up the synchronous sessions.

3. *Use multimedia when appropriate*. Online courses tend to be primarily textual-based forms of instruction. We have found that graphic images, photographs, and videos enhance student motivation. For example, in several of our courses we have created short QuickTime clips from popular movies and television shows that can be streamed over the web. These clips provide entertaining examples that support the concepts and procedures being discussed in class and provide a nice break from the textual format that dominates current online environments.

Information Overload

Providing too much information in a short period of time contributes to memory overload, which makes learning difficult and leads to confusion and poor retention. Psychological studies show that most people can manage about seven "pieces" of information at one time without too much difficulty (Miller, 1956). Instructional designers need to follow the *Rule of Seven*, which suggests that the amount of information presented at one time should be limited to no more than seven pieces of content (Clement, 1985). The Rule of Seven suggests that instructional designers "chunk" instructional content into small groups and give students the opportunity to learn each "chunk" thoroughly before being presented with new information. The following strategies have been used successfully in our online program.

1. *Limit the amount of content and activities*. By following the Rule of Seven, we help avoid memory overload by purposely limiting the amount of information and activities we provide in a course. For example, we ask instructors to break their lectures into 10-12 minute "chunks" or segments. These short lectures are recorded and converted into streaming media for delivery to students. These short lectures make it easier for students to complete in one sitting and it forces the instructor to concentrate on only a few main concepts in each "mini" lecture.

2. *Organize instruction around learning cycles*. The instructional design model used in the *HRE Online* program utilizes learning cycles at the core of its modular approach. Each learning cycle is comprised of three components. The first component provides the student with access to new content through a streamed audio or video file or by reading an online article. The last component of the learning cycle involves evaluating the learning outcomes through an activity involving self-assessment, peer-assessment, or formal instructor assessment and feedback.

3. *Provide a graphic organizer for the course*. It is very easy for students to get lost in any hypertext environment as they navigate through online courses that contain extensive layers of content distributed over multiple locations. To avoid the frustration and memory overload that can occur in a web-based environment, we provide a visual representation of the course structure. This graphic organizer serves as a map for students as they navigate through various portions of the course. The graphic is also hyperlinked so students can quickly move to a desired location in the course by clicking directly on the image.

Contextual Learning

Context is an essential central element in learning because knowledge is a product of the activity, context, and culture in which it is developed and used (Brown, Collins, & Duguid, 1989). Wilson (1993) identifies three major premises of context and how these affect knowing and learning. The first is the idea that learning and thinking are social activities that are structured by constant interpersonal interaction. Second, the available tools within the particular situation significantly structure an individual's ability to think and learn. Finally, "human thinking is profoundly structured by interaction with the setting" (p. 72). We offer the following recommendations to online instructors to promote contextual learning in the virtual classroom.

1. *Create virtual learning teams.* At the start of each new course, students are placed in a virtual learning team consisting of three to four other classmates. This allows the instructor to replicate the group experience found in face-to-face settings. Students work together on weekly assignments and projects via conferencing systems, conference calls, e-mail, and Instant Messenger.

2. *Simulate reality using appropriate case studies.* Regardless of the delivery format, the more "real-life" examples that can be utilized, the better students will learn. Case studies are an excellent way to provide the context through which new learning can be developed. As with any situation where a case study is used, it is critical to choose cases that relate to the content of the course.

3. *Require collaborative projects with schools, businesses, or other organizations.* Students are encouraged, where possible and appropriate, to develop course projects within the context of their work environment. This provides a real-life context in which to imbed application of the material. For example, in the online instructional design course, students develop a training package that represents 6-8 hours of training time. The majority of the students choose to develop a training package that addresses a performance issue within their organization.

Social Learning

Social learning theory combines elements from both behaviorist and cognitive theories and posits that we learn best by interacting with others in social settings (Merriam & Caffarella, 1999). Social learning is manifested through socialization, social roles, mentoring, and locus of learning.

For the social learning theorist, the purpose of education is for the learners to have new roles and behaviors modeled for them. Instructors and peers serve as a model for new roles and behaviors within an educational context. The following strategies have been successfully used by online faculty to promote this perspective.

1. *Create a personal connection with students.* Our goal is for instructors to be perceived as a real person in mediated communication. This is promoted several ways. Each course has an audio-streamed welcome message from the faculty member. This helps the student to put a face with the voice. Additionally, actions such as humor, vocal variety, personalizing examples, addressing students by name, questioning, praising, initiating discussion, and encouraging feedback all help make this connection. Personal connection can also be made through the use of "relational icons" or "emoticons" made by combinations of punctuation marks.

2. *Peer review and feedback.* Feedback from fellow students is as important as instructor feedback. Therefore, students in many online classes are asked to provide a meta-evaluation of another student's work. The purpose of the activity is to help their peers by providing comments that help the person understand the areas that are clear and well done and the parts that need further development.

3. *Require and facilitate interaction.* This may not seem like a new approach, however, in the online environment, it is much easier for students to be passive both in weekly assignments involving the group as well as during synchronous chat sessions. In addition to basing a percentage of the course grade on participation, other initiatives can be taken as well. One is to post an agenda of the upcoming week's synchronous session. Another technique is to post discussion questions prior to a synchronous session. Both approaches encourage students to think about the topic and be ready for a discussion.

Active Learning

Active learning can occur in many forms in an online environment. Discovery learning, project-based learning, and cooperative learning are common techniques for engaging students in activities that involve considerable amounts of creativity, decision-making, and problem solving. The following are specific examples of how active learning can be applied in an online environment.

1. *Organize online courses around projects.* Since HRD is a constantly evolving applied field of study, it is reasonable to design an online HRD course with a heavy emphasis on the application of the skills and procedures needed by the HRD professional. The best way to accomplish this in an online environment is through a project-based approach. Application-rich courses can be designed around major projects and specific activities to be completed in order to create a final product.

2. *Think-Pair-Share in a virtual environment.* Having online students work in groups of two or three within a virtual environment is a great way to keep students active and focused on their learning. Think-pair-share is an active learning technique used in many face-to-face classes but is rarely used in a virtual environment. The goal is to help students organize prior knowledge, brainstorm questions, or summarize, integrate, and apply new information. This strategy can be used in both synchronous and asynchronous situations.

3. *Use small group discussions during synchronous sessions.* We conduct weekly synchronous sessions in our program where the instructor performs a live audio broadcast to the students over the web while the students interact with the instructor and other students in a group chat space. While this in itself encourages active learning, incorporating small group interactions into the large group discussions further enhances it. This is accomplished by having the instructor describe a discussion activity to the class and then asking them to enter their private "virtual team" chat space to discuss and complete the assignment. A specific time is given when the students are expected to return to the class chat space and share the major points of their discussion with the rest of the class.

Reflective Learning

Mezirow (1990) defines learning as "the process of making a new or revised interpretation of the meaning of an experience, which guides subsequent understanding, appreciation, and action" (p. 1). Reflection allows individuals to correct distortions in their beliefs and critique "the presuppositions on which our beliefs have been built" (Mezirow, 1990, p. 1). The process of reflection enables the ideas, understandings, and experiences of individuals and groups to be reviewed (Preskill & Torres, 1999). Watkins and Marsick (1993) see reflection as a key to continuous learning. The following three strategies can be used to promote reflective learning.

1. *Provide extensive and timely feedback.* While this is something most instructors already know, it is important to remember that the online environment removes some of the human "checks and balances" that face-to-face students have with the instructor. While the opportunity to ask questions and have interaction with the instructor is relatively equal, feedback received through physical distance, eye contact, facial expressions and personal topics of conversation is not present for these individuals. Therefore, it becomes even more important that the instructor take time to provide feedback that is detailed enough to paint a complete evaluative picture.
2. *Incorporate "One Minute Papers" and "Muddiest Point" into class.* "One Minute Papers" are short writing exercises in which students are asked to reflect on a particular topic as a form of knowledge assessment activity. Students are asked to post a quick list of the new knowledge they gained through a particular session. The "Muddiest Point" activity allows students to identify the areas of confusion or uncertainly and/or to raise additional questions around the content of the session. Both of these activities benefit the students and instructor by providing feedback on what was clear and what may need further attention through the use of reflection.

3. *Online diaries or reflective journals.* Diaries and journals promote continuous reflection throughout the course. Entries can be self-directed or promoted by an issue, question, or experience posed by the instructor. Journals allow students to reflectively interact with various course topics and experiences and, as noted earlier, critically examine how their values, beliefs and attitudes fit with the material. This is a way that promotes growth beyond what regular instructor and student interactions provide.

Concluding Thoughts

The instructional strategy framework discussed in this paper is clearly a work in progress. Although the framework is based on well-recognized theories of learning and represents a synthesis of ideas from multiple perspectives, it is not fully developed, nor is it all-inclusive. Additional principles will be added as the online program continues to develop and evolve. The specific techniques for applying the instructional principles highlighted in this paper are currently in use in the *HRE Online* courses and continue to be enhanced each time they are implemented. The possibilities for application of the instructional strategy framework are only limited by the creativity and energy of the instructional designers and course instructors.

Formalized research efforts need to be conducted to validate and improve the strategy framework and the instructional techniques that evolve from it. Studies that examine the effectiveness of instructional strategies in online courses are lacking in the educational technology literature. Most literature provides anecdotal comments on experiences with online courses and empirical research that compares face-to-face and online delivery methods. Instead of comparing two dissimilar learning environments, future studies should empirically test the effectiveness of different instructional techniques in maximizing learning opportunities and achievement in online environments.

ECO TECH LINK
PT3 Grant Builds Technology Circles in the K-18 Community

Abstract: *Through the vehicle of the PT3 grant program, ECO TECH LINK has built a strong consortium to support technology circles of government, education and business in order to raise student achievement scores, shorten the time it takes to earn a teaching credential, and enhance the quality of teacher credential courses. The ECO TECH LINK grant enables targeted teacher candidates, including women, minorities, military and high tech professionals, to earn a preliminary teaching credential using a combination of online, face-to-face, video and extended field experience. Math and science curricula with environmental themes are the "real world" framework for online courses providing anytime and anyplace access. This paper describes the need, design, structure, progress and evaluation of the PT3 grant during the first year of implementation.*

Almost a decade ago, Goodland (1994) felt that "very little attention has been given to the role of reforming teacher education." Concurrently, the Office of Technology Assessment, in its report about teachers and technology to Congressional committees, acknowledged that the "interaction between K-12 schools and teacher education programs is an important, generally overlooked variable". (OTA, 1995) Recently President Bush projected in a press release, "A Quality Teacher in Every Classroom", that school districts across the nation will need to hire 2 million teachers over the next ten years. He announced an initiative that will provide a $2.85 billion grant program to enable school districts to recruit and train teachers and principals. In order to meet this challenge, educators have to be willing to accept that "our world is far more complex than ever before, and those who succeed are those who find new and creative ways to solve problems and open up new opportunities." (Segal, 2000)

With this background in mind, a strong consortium for reform in education consisting of government, education and business designed the ECO TECH LINK grant as a technology circle in order to raise student achievement scores, shorten the time it takes to earn a teaching credential in California, and enhance the quality of teacher credential courses. ECO TECH LINK builds upon the current capacity of the National University, the San Diego Natural History Museum and two high need school districts: Cajon Valley and Carlsbad. The PT3 (Preparing Tomorrow's Teachers to Use Technology) program awarded the grant to National University in July 2001 for a three-year implementation. Specifically, the grant restructures the online teacher preparation program at National University in California by implementing an intensive seven-month teacher-training program. The ECO TECH LINK grant enables targeted teacher candidates, including women, minorities, military and high tech professionals, to earn a preliminary teaching credential using a combination of online, face-to-face, video and extended field experience. Additional partners include Cox Communications; Datel Corporation; the Resource Conservation District of San Diego; U.S. Forest Service; the Environmental Trust; and the San Diego Water Authority. TELESIS Corporation will serve as the external evaluator.

National University along with Cajon Valley Union School District, San Diego Natural History Museum and Carlsbad School District modified present teacher education courses to create interactive web-based units. Math and science curricula with environmental themes are the "real world" framework for online courses providing anytime and anyplace access. Teacher candidates and college professors work with veteran K-12 master teachers to create meaningful standards-based methods courses using California State Content Standards and National standards for teaching and learning. ECO TECH LINK created training sessions that will be disseminated statewide using the thirteen National University regional campuses. During the second year of the grant, the California Commission on Teacher Credentialing (CCTC) will validate the seven-month teacher credential program and provide accreditation. Cox Communications will provide the infrastructure to connect the San Diego Natural History Museum and all classrooms via the new museum facility. Cox has agreed to donate video studio time and equipment for filming video clips as well as staff time, and Datel Corporation is committed to providing deeper orientation and training for existing and new hardware supplied to National University. Two groups are the main targets of recruitment for this unique program (1) military professionals who are transitioning to civilian life; and (2) high tech professionals who are transitioning from businesses that have had to down size. All teacher candidates will be working on graduate degrees. National University will assist candidates in establishing student loans and encourage placement of graduates at employment sites that qualify for loan reimbursement due to high levels of poverty based on statistics from the California State Department of Education.

Prior to selecting the sequence of courses and the avenue of recruiting, this PT3 grant held a Design Session workshop for all grant consortium members. The daylong session brought people together in a unique way as it provided the environment for participants to work in three teams to "Build-A-Model" using "Cause and Effect" diagrams based on the work by Dr. Edwards Deming in Japan. The diagrams describe each team's view of the effects they wanted to create through the grant process by carefully analyzing the causes of philosophy, culture, policy, and strategy on the possible success of the grant design. A booklet was developed from the workshop recording all concepts and key ideas. After the grant management team digested the information gleaned from the booklet, it became apparent that the original grant design needed to be refined to facilitate evaluation of objectives and their matching indicators for the PT3 Performance Reports.

Logic Model for PT3 ECO TECH LINK Project Evaluation

<table>
<tr><td colspan="7">Goal 1.0 To increase the use of technology in National University credential courses to produce pre-service teachers capable of delivering a technology infused curriculum focusing on science and math.</td></tr>

Goal 2.0 To increase the level of technology integration and application skills and resources in the K-18 classroom.						
"Teaching Digitally" curriculum; NU ed tech experts and Two school district & technology company partners; budget	e-College delivery via Internet; inventory & ed-tech equipment upgrade in targeted K-18 classrooms planned	# of NU faculty & # of master teachers trained via e-college; classroom technology upgrades completed	University Faculty; K-12 Master Teachers & Teacher Candidates; K-18 students	# Faculty and # Master Teachers Available to train/ mentor & evaluate teacher candidates increases	All participants have access to training via technology rich environments at the K-12 target schools	Level of technology integration, NU Faculty and Master Teacher skills and resources in K-18 classrooms increases

The logic model provided a road map for the management team to follow as they struggled with the scope of the project as each consortium member assumed responsibility for his or her part of the grant process. One of the greatest concerns became the infrastructure the consortium would have to put into effect as support for the pre-service teachers. In an attempt to put the task of recruitment of master teachers and pre-service teachers into perspective, the following questions were explored by the grant management team:

1. What are the roles, processes, purposes, and timelines required to modify the program sequence and enhance (revise) the courses? (See Inspiration Software document)
2. What are the criteria for selecting the Master Teachers? Who determines the criteria?
3. Who are involved in the selection process of Master Teachers?
4. When are Master Teachers selected?
5. When and how are Masters Teachers prepared?
   (create a community of learners that meet continuously)
6. How are NU and K12 course designers/enhancers selected?
7. Are teacher candidates placed in a few selected schools? Would such placements encourage a strong learning community?
8. How can we create on-ground and online community of learners among and between teacher candidates and Master Teachers?
9. Are multiple subject AND single subject teacher candidates recruited?

The next step was to clearly define the possible course sequences that would ensure high quality and rigor in the teacher credential program while shortening the students' timeline for completion. During each month for the first two months, pre-service teachers take two online methodology courses a month. In the third month, they begin their student teaching during a full day of school activities in the classroom. In the afternoon they take one online theory course per month in the computer lab at the school where they are doing their student teaching. The paradigm shift in this model is two fold: 1) students take the methodology courses before they take their theory courses; and 2) the curriculum from the theory courses in the afternoons can be implemented the next day in the classroom. After adding the Student Teaching Seminar, plus the fact that student teaching is 18 weeks long in California, the original plan of 6 months for training became 7 months, as shown in the table below.

Month	Multiple Subject Certificate	Single Subject Certificate
Prior to 1	CLD 600 Early Field Experience	CLD 600 Early Field Experience
1	CLD 615 Educational Foundations EDT 608 Computer Based Technology	CLD 615 Educational Foundations EDT 608 Computer Based Technology
2	CLD 605 Diverse Classroom CLD 611 Applied Psychology to Teaching	CLD 605 Diverse Classroom CLD 611 Applied Psychology to the Teaching ...
3	CLD 629 Student Teaching Seminar	CLD 629 Student Teaching Seminar
4	CLD 630A Student Teaching CLD 621A Methods for Language Development in 1st and 2nd Language	CLD 630A Student Teaching CLD 623 Teaching English Language Development
5	CLD 630B Student Teaching CLD 621B Methods for Language Arts and Teaching of Reading	CLD 630B Student Teaching CLD 624 Reading in the Content in Subject Area
6	CLD 630C Student Teaching CLD 622A C and I: History-Social Science, PE, and Visual and Performing Arts	CLD 630C Student Teaching CLD 625A Curriculum and Instruction
7	CLD 630D Student Teaching CLD622B C and I: Math and Science	CLD 630D Student Teaching CLD 625B Classroom Management

The decision making process modified the original grant logic model to include a pilot cohort of student teachers as a baseline instead of the larger group of 50 students initially planned. A new university policy mandating that students must pass applicable subject matter exams prior to the 5th credential course was one factor in this decision. The pilot cohort began with 10 teacher candidates, with the anticipation that grant program would enroll at least 50 teacher candidates each time at National University. Cajon Valley Union School District provided master teachers and K-8 school site placements for the pilot teacher candidates. Carlsbad School District provided master teachers and assisted in the placement of teacher candidates. The San Diego Natural History Museum – Museum to School Partnership Program: Communities Alive In Nature (MSP/CAN) provided science and ecology training to master teachers in order to help National University professors rewrite methods courses during the technology training sessions.

Three collaborative technology sessions were planned for the first year of the grant, with the agenda being driven by the technology needs of the master teachers in integrating multimedia and critical thinking skills into their daily curriculum. During the technology training sessions, participants formed small working groups with at least one master teacher, one student teacher and one National University professor. Each working group selected a grade level to write for, based primarily on the master teacher's area of expertise. This classroom grade-level experience was then integrated into the National University technology courses, making the courses more practical and useable for the teacher candidates. The master teachers knew the types of information that would be most directly useful in the classroom situation. The university teachers knew what outcomes were expected in the university course. The student teachers provided a point of view based on their freshness, enthusiasm and lack of exposure to the classroom.

At this point, the excitement began to build. The technology training provided by the workshop was viewed as beneficial for all participants. However, the real excitement was having time to work with peers on a technology project that would have a positive effect on thousands of future teacher candidates while developing working relationships among public school teachers, student candidates and university teachers. The master teachers were pleased their expertise was valued, and their voices were heard. The university teachers were most appreciative of these voices from the front line: the classrooms. The student teachers quickly immersed themselves in the technology project and steadily developed a feel for what was needed in the classroom, both at the public schools and university level. The "give and take" experienced by participants was such a pleasant energizer that all participants agreed to continue the process with other projects.

As a result of this technology training, the university courses now contain specific threads and assignments at distinct grade levels. Thus a candidate who is interested in teaching at the fifth grade level can follow the thread for that level and develop practical, as well as theoretical, knowledge specifically designed for fifth grade students. This knowledge becomes the beginning of a portfolio for student teaching. It is information based on actual classroom knowledge, and the master teachers are able to see their work become part of university courses.

Eco-Tech Link Outcomes Evaluation Plan Progress

The following information lists the goals, outcomes, and major activities during the first year of the grant implementation.

Goal 1.0 To increase the use of technology in National University credential courses to produce pre-service teachers capable of delivering a technology infused curriculum focusing on science and math.

Outcome: Model blended curricula for the National University (N.U.) teacher-credentialing program and K-12 classrooms are created which meet the State of California (CTAP) and national standards for educational technology competencies.

Major Activities: During the first technology training session, master teachers and NU faculty were divided into teams to evaluate the NU designated clearing credential course for California pre-service teachers: EDT 608 (Computer-Based Technology in the Classroom). They were given access to the online class template and asked to take the course as if they were a pre-service teacher in an interactive technology environment. Their feedback on how to enhance the course with science and math curriculum was discussed as a group, recorded on paper and provided to the management team for implementation. Many of the recommendations involved integrating student activities at multiple grade levels of K-3, 4-6, and 7-8 into the teacher-credentialing course to facilitate transference of material from the online courses into the classroom the next day.

During the second technology training session, emphasis was put on enhancing a teacher education credential courses. The first online course was reviewed, and the collaborative group applied their recommendations for enhancing CLD 625A (Curriculum and Instruction) in the areas of science and math as a model for three other classes: CLD 625B (Classroom

Management), CLD 622A (History-Social Science, PE and Visual and Performing Arts), and CLD 622B (Math and Science). Grant participants researched sources on the Internet on how to use technology to integrate science and math activities into curriculum that addresses standardized assessment tools, self-esteem, trends in assessment, and instructional planning skills. Application software skills became the successful organizational tools for this training session as the teams worked together on a beginning outline for each course. A ten-hour homework assignment completed the training session, allowing for reflection and additional research.

Goal 2.0 To increase the level of technology integration and application skills and resources in the K-18 classroom.

Outcome: ECO-TECH LINK Program participants have access to training via technology-rich environments in the K-12 target schools.

Major Activities: Technology training sessions were held to assess and increase the computer literacy levels of the master teachers and NU faculty in this grant. The grant participants, using the California Technology Assessment Profile (CTAP), took an online Pre-Test to measure their level of technology integration and application skills. The CTAP measures basic hardware; software packages and terminology; research tools; ethics and policies; information literacy; integration, student learning, and classroom management; communication through print media; and instructional technology in the areas of analyzing best practices, selection of appropriate technology resources, matching student learning styles to appropriate resources, effective learning environments, and security issues. A Post-Test will be given in June to complete the evaluation and research.

The grant management team performed a technology need assessment of master teachers in Cajon Valley School District and for NU faculty and later for the Carlsbad master teachers. The decision was to hold the training sessions in both Macintosh and PC labs to accommodate both levels of education. The first technology training session was held in a middle school setting with Macintosh computers; materials were developed for multiple levels of expertise among the master teachers. The first training included: follow-along exercises in PowerPoint with extensive screen captures and instruction; CD ROMS with text, videos, music, graphics and sounds for teachers to use as resources in the training and later in their own classrooms; a PowerPoint show based on the Wizard of OZ, demonstrating advanced skills in multimedia; an Internet Scavenger Hunt to teach research skills for a K-8 classroom setting; "value-added" Internet research using Web Quests; new web resources with images to meet the needs of developing Natural History Museum MSP/CAN projects with science emphasis for K-8 classrooms; file management; creating hyperlinks in documents; Acceptable Use Policies (AUPs) for school districts; digital camera usage; inserting images and sounds into projects; research on "how to design" rubrics based on examples from the Web; Web page creation in Word with graphics, text, tables, hyperlinks and HTML format, coupled with hands-on technical assistance. A wrap up session occurred at the end of each day to read the participant feedback forms to determine what went well and what would be needed in the next training session for both master teachers and NU faculty.

The second technology training session was held at the state of the art NU facility with a PC classroom. The change in platforms went seamlessly. The participants were amazed at how easy the PCs were to run and were able to cross platforms immediately. Information sessions and follow along structured exercises supported such topics as: search engines for the Web; Show and Tell presentations for Natural History Museum MSP/CAN electronic projects; a supervised library tour focusing on electronic databases, resources and ebooks; creating matrices and calculating percentages with graphs in Excel; web research for multimedia projects for the K-12 classrooms; and a videotaped walkthrough unveiling the improvements to the EDT 608 course, which they had evaluated and enhanced with activities in the first training session in January 2002.

The third technology training session was held to provide student teachers with similar technology skills and resources to integrate immediately into the student teaching classroom. It focused extensively on advanced PowerPoint multimedia and Web Quests, using screen captures again in the training materials with detailed, hands-on instruction. Master teachers and NU faculty were invited but not required to attend this session. In addition, the focus was on creating PowerPoint presentations that could be integrated into their daily lesson plans.

Goal 3.0 To expand and sustain the ECO-TECH LINK partnerships over the next 3 years.

Outcome: ECO-TECH LINK model is institutionalized statewide via nine regional National University sites and partnerships.

Major Activities: Enhancing just one of the teacher credential courses through this grant (EDT 608) has already benefited hundreds of students over the nine regions of California since the new version is currently being taught online. The enhanced course was offered online in March and April 2002 to a total of over 350 NU pre-service teachers who have to clear their California Clearing credential. The same amount and kind of students at NU will take the course in May and June 2002, raising the number to 700 of pre-service teachers who have completed the course with the new design from the grant. Beginning in July 2002, the EDT 608 course is no longer the clearing course for technology. Instead, at NU, it has been embedded in all teacher education credentialing programs, with an anticipated enrollment of 7,000 students a year, meeting the needs of school districts for science and math curriculum integrated with technology.

Goal 4.0 At least 80% of the pre-service teacher grant candidates will complete the ECO-TECH LINK program in seven months.

Outcome: At least 80% of the pre-service teacher candidates will complete the ECO-TECH LINK program in seven months. This goal will be measured every seven months on completion of a cohort group through their teacher credentialing cycle.

Major Activities:
None at this point because the grant management team redesigned the grant design process and inserted a prototype group of 10 pre-service teachers as a baseline group.

Goal 5.0 To expand the population of women and minority candidates who become fully credentialed pre-service teachers able to infuse technology in a science and math based curriculum.

Outcome: 80% of women and minority teacher candidates in each cohort will complete pre-credential requirements in seven months.

Major Activities:
None at this point, but plans are being made for innovative ways to support this population to ensure a high level of completion such as mentoring, cohort leaders, family oriented activities, and a new course in classroom behavior management taken prior to the student teaching experience.

Abstract: An educational digital environment that will provide appropriate methods and techniques for the support and enhancement of the educational and learning process is a valuable tool for both educators and learners. In the context of such a mission, the educational tool SL-EDGE (Student Library-Educational DiGital Environment) has been developed. The application employs, amongst others, a standardized metadata structure and collaborative filtering techniques in order to provide a set of educational services oriented towards users' needs for the discovery and reuse of educational resources for a reliable, efficient and effective assessment and also for communication, distribution and exchange of ideas and opinions. To this effect, it consists of two main modules: an educational digital library and an assessment tool for teachers and students. All the functions implemented are fully web-based and the application deploys technologies such as Java, JavaServer Pages and JavaBeans, transforming it to a powerful and robust educational tool.

Keywords: digital library, assessment, metadata, standards, collaborative filtering, education.

Introduction

The Internet and its software applications have become the de-facto information access and distribution system of the new millennium. However, the exponential growth of the World Wide Web and the continual augmentation of the available information resources have resulted to many problems due to the lack of standardized structures and typologies for content description. Moreover, the coverage of Web content by search engines is continually decreasing, and the full-text approach to searching has become increasingly ineffective due to the rise in non-textual information online. As a result, the search engine approach generally suffers from low precision and problematic information retrieval.

To address these problems, much recent research has focused on building web-based digital libraries containing vast repositories of information resources. Within educational applications, a primary goal of these libraries is to provide users (teachers and students) with a way to search for and display digital learning resources commonly called "learning objects". Examples of such educational digital libraries include the instructional system for the science, mathematics, engineering and technology education SMETE community (Dong et al., 2001), the open-source digital library software Greenstone (Witten et al., 2001), the Digital Libraries Initiative Project by the University of Illinois (DLI), the Libraries Special Collections Project by the North Carolina State University (LSC), the Pennsylvania Education Network Digital Object Repository (PEN-DOR) system by the University of Pittsburgh (Fullerton et al., 1999) and many more.

As part of these efforts, researchers are developing digital library systems that provide descriptive summaries intended to convey the semantics of an object. Together, the data elements of these summaries usually comprise what is called a metadata structure. Hence, in typical educational digital library applications, learning objects are stored and labeled with a metadata record. This metadata record usually contains basic information about the object including, for instance, technical requirements, rights management, and author details. Metadata structures are searchable and thus provide a means for discovering, sharing, and reusing learning objects, even when these objects are non-textual.

In this paper, we examine key assumptions underlying the design of an educational digital library coupled with a metadata structure and we demonstrate an implementation of the ideas discussed above within a system called SL-EDGE (Student Library-Educational DiGital Environment). In particular, we present the fundamental notion according to which a learning object can be effectively described with metadata elements and then retrieved via these descriptions in order to be used or reused in a new learning context.

As far as the effective description of learning objects is concerned, we argue that this incorporates the use of an appropriate metadata structure that will describe the semantics of a learning object and will also ensure the desired syntactic and semantic interoperability among other similar applications. Many efforts have been accomplished by organizations, groups and committees for the creation of standardized metadata element sets, which can offer these important capabilities to the applications that use them. The most important efforts include ADL organization (ADL) with SCORM specification (SCORM), ARIADNE project (ARIADNE) with a corresponding specification (ARIADNE version 3.1), CEN/ISSS Learning Technology Workshop (CEN/ISS), IEEE Learning Technology Committee (IEEE) with the Learning Object Metadata specification (LOM), IMS Global Leaning Consortium (IMS), ISO Joint Technical Committee (JTC1) SC36 (SC36) and many more. These efforts focus on issues such as controlled vocabularies, architecture, educational activities, metadata for learning objects, systems for course administration and technologies for student and teacher communication, cooperation and collaboration. The metadata structure used by SL-EDGE complies with the metadata element set that has been established by the Dublin Core Metadata Initiative (DCMI), a group of scientists that are responsible for the development, standardization and promotion of the corresponding Dublin Core Metadata Element Set (DCMES)(Baker, 2000).

We also argue that the semantic information about each learning object captured by the metadata structure described is critical in supporting effective discovery and reuse of learning objects for instructional purposes. A mechanism that uses this information in order to offer extended search capabilities, using expanded queries and corresponding browsing facilities, should be and is indeed provided by our application.

Furthermore, the application captures information about the users and their preferences, which is further exploited by a suitable collaborative filtering algorithm. We describe and discuss the application of a collaborative filtering technique in order to support automatic filtering and recommendation of relevant learning objects for SL-EDGE and we illustrate how the information about a learning object can be comprised of community-contributed information as well as usage metrics. This approach supports the automatic recommendation of relevant learning objects and allows the user to locate other users with whom shares similar interests for further communication and collaboration. The result is the creation of communities through evaluating and using learning objects and the reinforcement of the reusability of the learning objects.

As an essential and supplementary tool for the educational digital library with the above characteristics, an assessment module has also been introduced. Its purpose is to complete the learning procedure and provide evidence of good implementation of teaching methods and teachers' practices and of the overall comprehension and understanding of a certain educational domain on behalf of the students.

In the next sections we will discuss in detail the two modules presented above, the procedures they include, the practices they implement and the benefits they provide to teachers and students, the two major links in the educational chain.

Educational Digital Library Module

The main function of the educational digital library module is the dynamic construction and presentation of collections of educational materials, commonly known as learning objects. The system gives teachers the ability to build such collections with effective full-text searching and metadata-based browsing facilities that are attractive and easy to use. Moreover, they are easily maintained and can be enriched and administered in a semi-automatic way.

A learning object is any digital entity, which can be used, reused or referenced during a learning activity (LOM). It can be text, pictures, or other multimedia formats. The application collects learning objects and semantic information about them using a number of metadata. As mentioned above, in order to ensure the desired semantic interoperability, the standardized Dublin Core Metadata Element Set is being used. According to this set, metadata such as author, title, description, date, keywords, category and technical features (resource size and format) are associated with each learning object. These are the raw material for indexes and are used to support searching and browsing facilities. They are explicitly provided by the contributor who completes the corresponding forms.

Searching utilizes indexes from the above metadata such as title, description, author names of learning objects and also category title and keywords, the selection of which is used to create expanded queries. The search interface is a simple one, suitable for casual and advanced users. It allows term and phrase searching and also stemming control.

Browsing utilizes metadata such as category title and subject. Users when browsing, examine a dynamic hierarchical classification scheme, in the form of a tree structure, created by these metadata. Each learning object is classified into the categories and subcategories of this scheme (Fig. 1). Browsing is particularly helpful for inexperienced users not familiar with a subject, its structure and terminology (Koch et al., 1999).

Title: Reasoning About Resources
Category: 03. Algorithms and Complexity
Description: Notes from Dartmouth University on algorithm complexity
Authors: Theodore Kalampoukis
Keywords: Algorithms
Contributor: Antonia Kyriakopoulou
Creation Date: 2001-11-09

Figure 1: Summary of a learning object's metadata and relevant user functions

The result from searching or browsing is a number of learning objects. In case of searching, the retrieved learning objects are displayed ranked according to the number of occurances of the search terms in the metadata records. In case of browsing, the system retrieves the learning objects that are classified under the category selected by the user and under the children-categories by traversing the branches of the tree structure. The displayed learning objects are sorted by metrics related to their popularity, i.e. their visiting rate.

The selection of a learning object displays the summary of metadata associated with it (Fig. 1), and gives the user the ability to add it to "My Favorites", to view and reply to existing comments or create new ones, to create personal annotations and to download the resource to his/her system. Last but not least, the user can rate the learning object using a Likert scale from 1 (minimum) to 5 (maximum), and can also find relative statistical evidence such as the total number of users who have rated it, the percentage of users who have rated it at each point of the scale, and the average attained variation.

The above capabilities and information create what we call "user profile" for each user (Fig. 2). This contains information about the user (name, surname, e-mail, etc.), links to "My Favorites", replies to comments created by him/her and corresponding personal annotations. The most important aspect of a user profile is that it captures non-visual information concerning the learning objects visited by the user and the rates awarded.

BEST COPY AVAILABLE

A suitable collaborative filtering algorithm based on the approach of the "nearest-neighbor" (Recker & Wiley, 2000) further exploits the above information about the users and their preferences. This particular approach concerns the selection of a subset of users according to their similarities in certain parameters. Specifically, users with high correlation in relation to their rating of the same learning objects are treated as having the same interests and they construct the so-called user's "active neighborhood". After the creation of the user's active neighbor, the learning objects that have received high marks from the users of the neighborhood are recommended to him/her as relevant learning objects. In this way, the approach supports the automatic recommendation of relevant learning objects and allows the user to locate other users with whom shares similar interests for further communication and collaboration. The result of the above procedure is the creation of communities through evaluating and using learning objects, as well as the reinforcement of the reusability of the learning objects.

Information about the user

Users can view favorite learning objects, answers to their comments, personal annotations regarding a learning object and the community of users they have created

Figure 2: The user's profile

The system also includes an "administrative" function whereby users with administrative privileges can register new users and also manage the classification scheme and the collection of the application by inserting, updating and removing categories, subcategories, learning objects, authors and keywords. The interface of the application appropriately supports these functions. The module has many automatic features allowing simple, novice users to use it and make the most of it.

Assessment Module

The assessment module provides two interfaces, one for the teacher and one for the student, with appropriate functionalities and capabilities. Specifically, the teacher creates questions, constructs assessments and tests from sets of questions, assigns them to particular students or groups of students, reviews results and sees statistics and other evidence of comprehension and progress. The student on the other hand, sits for the test online on dates that have been set by the teacher and sees the automatically generated (where possible) results. The results are presented in various ways (graphically, etc) and the student can also see the right answers to the

BEST COPY AVAILABLE

tests already taken and any available feedback given by the teacher. Last but not least, the system lets the students keep track of their progress and compare their overall performance with that of their classmates.

Going into details, the process of constructing an assessment includes a set of steps. First, the teacher creates the questions of the test. The types of questions currently supported by SL-EDGE are (Fig. 3):

- Multiple choice
- True/False
- Fill in the blanks
- Open-ended

The process of creating a question includes composing the question itself, the possible answers, the right answer(s) and the marks that will be added to the student's final score if answered correctly. Also, the teacher has the option to add feedback to each question to be supplied to the student after test completion. According to the type of question selected, a corresponding form with appropriate guidelines is presented to the teacher to fill in. After being created, the question is submitted to the central point of the module, the question pool. Assessments and tests are created by drawing questions from the question pool (Fig. 3). The teacher can choose from the new questions that he/she has submitted following the procedure discussed above, and/or from the already existing questions. This means that a question can be used for the construction of various tests, something that is in favor of reusability, achieving minimum authoring time and maximum flexibility. An assessment consists of an open-number of questions and also includes information such as title, date of fulfillment and guidelines for the students. Assessments can be viewed from the corresponding assessment pool.

Figure 3: The Question Pool

All assessments can be removed or updated by adding or removing questions and updating related information. Accordingly, questions can be removed and updated too. These functions require that their executor is indeed the creator of the assessment and/or question. The deletion of a test doesn't lead to deletion of the questions that form it; questions that are included in assessments cannot be erased.

The teacher's interface also includes a mechanism for receiving and evaluating the answers to the open-ended questions that a test might have and for sending back the corresponding scores.

BEST COPY AVAILABLE

The student's interface is where the tests are taken. All questions of a test are presented in the appropriate format. The student can navigate back and forth the questions and give his/her answers. Immediately on completion, the results are automatically extracted along with the right answers and the feedback supplied by the teacher. Only open-ended questions are sent back to the teacher for review and evaluation.

Both interfaces include a mechanism for viewing the results of the tests and keep track of the progress. The system provides for the creation of reports of progress in many formats (charts, graphical representations, etc).

In conclusion, the assessment module provides an automated, wizard-like environment for the creation of questions, the construction of a test and its assignment to specific students or groups of students and the review and extraction of results after its completion.

System's Architecture and Technical Features

The system follows the 3-tier architecture model with a relational database for the data storage layer, Java, JavaBeans and JavaServer Pages (JSP) for the application layer and HTML and JavaScript for the presentation layer.

Also, the system adopts the Struts framework for building Web applications that integrates with standard technologies like the ones mentioned above. This encourages application architectures based on the Model-View-Controller design paradigm (Struts).

Last but not least, the Unicode character set is used throughout so that learning objects, tests and interfaces can be in any language. Learning objects and tests have been produced in English and Greek, and SL-EDGE has interfaces in both languages.

Conclusions and Further Research

The increase of the available information on the World Wide Web and the penetration of web technologies into the educational sector have led to an imperative need and an absolute requirement for the development of tools that will support effective searching and indexing capabilities and will offer rich environments for the uplift of the learning process together with a knowledge management potentiality.

Digital libraries are good examples of the investigation and research of new approaches related to the effective use of huge information repositories, due to the tradition shared by the simple conventional libraries on supporting the information needs of their users. The digital library module of SL-EDGE incorporates a variety of technologies that provide consolidation, organization and access capabilities on large information volumes and presents heterogeneous information resources distributed over the Internet to look like a unified, homogeneous and integrated information resource. The system not only successfully supports the storage of learning resources but also the systematic knowledge acquisition related to its content and the user's preferences and behavior.

The use of metadata for the description of the classification scheme and the learning objects provides adequate support for the searching and browsing mechanisms. The metadata records created, describe in a successful way the educational context in which a learning object is to be used, reused or referenced. Also, the standardized Dublin Core Metadata Element Set adopted ensures the desired syntactic and semantic interoperability. This particular set has turned out to be simple but adequate for the library's needs; it is now one of the most popular and well-known standards and is given great support from the market (DC projects)(DC tools). To eliminate the time consuming procedure of metadata creation for each learning object, we only used a subset of the DCMES for the administration of our collection. The use of a number of automated forms with pop-up windows, drop-down lists, etc. optimized the process.

The implementation of the collaborative filtering approach adds a knowledge management view to the content and the library that derives from recording and further analyzing the user's "behavior". The approach manages to support the automatic recommendation of relevant learning objects and gives to the user the ability to locate other users with whom shares the same interests for further communication and collaboration. The result of the above procedure is the creation of communities through using and evaluating the learning objects of the collection and also the increase of the reusability of learning objects. However, for the further exploitation of this capability we suggest that in the future the system should provide a mechanism that will give greater motivation to the users in order to rate the learning objects they visit and provide more feedback for the collaborative filtering approach (Jones, 2001).

As far as the assessment module is concerned, this tool has succeeded beyond our expectations. It has been proved easy to use and manage for both teachers and students, optimizing the assessment procedure in all its phases, from the creation of a test until its final evaluation. The preparation time has been minimized by the ability of reusing already existing questions and tests whereas the wizard-like environment permits even casual users make the most of it.

Further research encompasses fundamental issues surrounding the concept of ontologies and knowledge acquisition. An ontology can be used to describe a piece of reality; it is referred to as "a specification of a conceptualization" (Uschold, 1996)(Uschold & Grüninger, 1996). It is typically conceived and expressed as a set of concepts (for example entities, attributes and processes), their definitions and their inter-relationships (RichODL-OU-3/1999). In the next version of SL-EDGE we are planning on creating an ontology that will describe the educational domain and will maximize the results from the use of the techniques and methods described above. In particular, we are concerned with how to incorporate the concepts of personalization and adaptability to the users' needs into the services offered by our application.

Another future extension of SL-EDGE is the development and integration of digital portfolios. Research up to now, has revealed that digital portfolios' main purpose is to constitute an alternative way of assessing students' progress by storing their scores and other material results. This information is then used as evidence of the learning acquisition and outcome. However, we believe that digital portfolios can be of wider use than just used for the assessment of the students' progress. If we approach digital portfolios from a knowledge management point of view, the results that they contain can be shared and distributed over the intranet and/or the Internet (Tillema, 1998).

SL-EDGE has been being used for over six months as a pilot program hosting learning resources from the courses of "Data Structures" and "Information Retrieval Systems" held in the department of Informatics in our University. The users registered are students that attend the courses and reach the number of 150. These are the simple users of the application with capabilities of searching and browsing learning objects and conducting assessments. Also, there is a number of users registered that play the role of the authors and/or contributors of the learning objects and that of the creators of the assessments. These are the professors of the courses and the assistants conducting the corresponding tuitions. Until now, up to 70 learning objects appropriately described with metadata records have been inserted and three assessments per course have been conducted. The general feelings we received from the users were very encouraging since they remarked on an increase of productivity and a very easy adaptation to the features and functions of SL-EDGE. Also, its property for keeping track of progress turned out to be very helpful.

We believe that the capabilities, techniques and user services presented in this paper contribute to the success of an application like SL-EDGE, which constitutes a useful and essential tool for tutors and learners.

Means and Methods in Automatic Courseware Production: Experience and Technical Challenges

Tobias Lauer, Thomas Ottmann
Institute of Computer Science
University of Freiburg
Germany
E-mail: {lauer, ottmann}@informatik.uni-freiburg.de

Abstract: Experience has shown that the production of rich-media content for web-based courses tends to be extremely cost and time consuming. One way for campus-based universities to reduce authoring costs is to automate the production process by using suitable tools for capturing live lectures. In this paper, we describe different technical approaches to presentation recording. Recording systems can be evaluated with respect to a number of criteria, such as recordable input formats, automatic structuring of captured contents, synchronous replay of graphical annotations, and many more. We present a list of these criteria and give an overview of several existing software tools. We also address features which are not supported by the currently available systems but which we consider important for a widespread acceptance of presentation recording, such as more comfortable system-user interaction or a both powerful and efficient representation of electronically captured handwriting.

1. Introduction: Online vs. Offline Teaching

Campus-based universities are used to offering their courses in the traditional, time and space bound mode to their students. At least in systematically structured subjects like science and engineering, including computer science, the whole organization of the curriculum follows the traditional workflow: Lecturers present contents in ex-cathedra lectures; we call this the presentation phase. These lectures are usually accompanied by tutorial sessions where weekly or biweekly assignments submitted by the students are discussed. Finally, in a third, also clearly identifiable phase of the learning cycle, students apply their acquired knowledge in project and thesis work. This way, universities are able to adapt their knowledge mediation to recent research developments in a quick and flexible way.

On the other hand, the ubiquitous availability of the Worldwide Web has had the effect that even campus-based universities are increasingly trying to loosen the time and space constraints of their studies by offering web-based courses. However, they experience that running courses in a distance mode requires a complete structural change of the traditional workflow. The different phases of the learning cycle are interweaved in a fine-granular manner; not only tutorial guidance over the net but all administrative and management tasks have to be handled in a new way for off-campus students. The most unpleasant experience, however, is that courseware production and implementation can be extremely expensive and time consuming. Experience gained in several large-scale projects in Europe has shown that production costs for rich-media content in the range between 50,000 and 100,000 EUR per weekly lecture hour are no exceptions. A successful strategy to virtualize parts of the curriculum at campus-based universities should therefore not only follow the traditional workflow more closely but must also drastically reduce the production costs of web-based courses.

One first step in this endeavor is to capture the media streams occurring in live presentations and integrate them to form synchronized multimedia documents for offline use. In the following, we describe different technical approaches to this process known as presentation recording. We provide a list of criteria according to which presentation recording tools may be compared and give an overview of several existing systems. We will draw on our own experience from the past years of capturing real-life university courses using our own recording technology. Finally, we shall address some challenging aspects that are unsolved in most of today's presentation recording systems. The technical problems to be solved in this context also concern the user interface for lecturers and methods to represent and compress electronically captured handwriting efficiently.

2. New Option: Presentation Recording

Presentation recording is by no means restricted to one particular technical approach. There is, in fact, a variety of technologies used in the systems that can be found in research projects and on the market today. When talking about presentation recording, the first thing coming to a lot of people's minds is taping a course with a video camera. That way, even traditional blackboard-and-chalk lectures can be made available by turning the recording into a streaming-media document and storing it on a streaming server. This way of recording is pleasing for the lecturers. They can keep to their usual way of teaching, do not have to adapt to new technology and are thus able to fully concentrate on the contents. We have experimented with this method and made the experience that acceptable quality can be achieved only if a large amount of personal and technical effort is invested both during and after the lecture: Skilled technical staff must be present for taking the video and audio recordings, the video must be enhanced by high resolution digital images of the blackboard in order to increase readability, and the recording has to be structured into meaningful sections manually. We do not see how all the necessary steps may ever be fully automated such that videotaping will become a feasible method for virtualizing live lectures. Similar arguments also apply to videotaping lecturers using overhead slides.

Using a computer-based presentation system fortunately offers more attractive alternatives for presentation recording: Instead of a video camera, the computer can take care of capturing the lecture, and in much better quality. Of course, some additional hardware is required, such as a (wireless) microphone and a suitable input device like touch-sensitive whiteboards or pen-sensitive LCD tablets. Occasionally, a small amount of extra preparation may also be necessary, like converting slides to a different format, but in general, the workload remains the same as it is without recording, and no support personnel is required during the lecture.

Regarding the recording software, there are at least three different alternatives. One is to make use of existing presentation systems and add a recording functionality. Examples include PowerPoint's built-in narration option, or MS-Producer for PowerPoint (Microsoft 2002). The resulting documents may preserve all the features of the original presentation or just consist of static pictures, depending on how the slides are processed during recording.

Another approach is screen grabbing. The capture software records any screen or window content together with the instructor's audio, producing a synchronized video output. An examples hereof is Camtasia (TechSmith 2002). The definition of this approach can be extended to include "output grabbing" in a more general sense. Instead of recording bitmaps, it is also possible to store transmission protocol information, as is done in the University of Trier's VNC-based TeleTeachingTool (TTT 2002) and in the University of Mannheim's RTP/I-based Interactive Media on Demand system (Hilt et al. 2001).

A third approach is to use a tool specifically designed for the presentation and recording of course contents, providing features that are particularly useful for this task. Our own recording system, Authoring on the Fly (Müller & Ottmann 2000), and its commercial descendant, imc Lecturnity Suite (imc 2002), are examples of such an approach, as are PresenterONE (Accordent 2002) and Georgia Tech's eClass project (Brotherton 2001).

Blendings of different approaches can also be found such as the system proposed in (Dal Lago et al. 2002), which synchronizes the instructor's video with a second video stream for class materials, which can be imported from any video source like overhead camera, PC, VCR, or others.

3. Criteria for the Evaluation and Comparison of Presentation Recording Systems
